EXTRAFAMILIAL CHILD MOLESTATION

Child molestation is legal term that designates a crime involving a range of indecent or sexual activities between an adult (or someone older than the victim) and a child. Although the age of the child victim may differ across states, such crimes usually involve a child under the age of 14 years. *Extrafamilial* molesters have abused a victim or victims who are unrelated to the offender, whereas *intrafamilial* molesters have abused family members. *Pedophilia* is recurring sexual fantasies, urges, or behaviors involving prepubescent

children. Not all pedophiles are child molesters because some pedophiles have not acted out on their sexual proclivities. Nor all child molesters are pedophiles because abusive sexual behavior toward children can be motivated by opportunism and impulsivity rather than by intense arousal or preference for children. This entry discusses the differences between child molesters and rapists, differences among child molesters, etiological models of child molestation, predictors of recidivism, and assessment and treatment.

Although the legal definition of child molestation focuses exclusively on the age of the victim, research definitions also take into account the differential age between the perpetrator and the victim to more accurately differentiate child molesters, rapists, and age-appropriate sexual behavior. Researchers operationally define child molestation as sexual activity with a minor who is younger than the perpetrator by a specific number of years. Although this tactic attempts to rule out confusion about the determination of child molestation versus *statutory rape* (sexual abuse of a postpubescent minor), it is still problematic because children's sexual developmental trajectories vary considerably. A 14-year-old girl may look like a 10-year-old, whereas her same-aged friend may look more like a 16-year-old. The Tanner Scale has been used in psychological research to improve classification by focusing on primary and secondary sex characteristics, such as breast development and testicular volume. This scale better differentiates victim's sexual development characteristics, and researchers have combined this scale with sexual arousal measurement tools, such as penile plethysmography, in an attempt to understand how offenders with various age preferences differ (e.g., *pedophilic* [children under 12 years or Tanner Scale 1], *hebephilia* [children at the early stages of puberty between ages 12 and 14 years or Tanner Stages 2 and 3], *ephebophilia* [postpubescent minors, Tanner Stages 4 and 5]). Because only victim's age is typically available in most record sources, this improved differentiation is often difficult to use.

The definitional complexities and motivational pathways among those classified as child molesters result in the de facto creation of a heterogeneous group of offenders whose diverse attributes are not captured by a single profile. Indeed, the

variations among them are important in etiological models, treatment planning, and risk evaluation. Coupled with the problem of the low frequency of reporting child molestation, these definitional discrepancies make it difficult to estimate the prevalence of child molestation in general and extrafamilial and intrafamilial in particular. Using data from adult surveys, plethysmographic studies, and general research on child molestation, Michael Seto in 2008 estimated that the upper limit of pedophilia in the population was 5%. The actual estimate of child molestation is problematic. In 2008, Seto's review indicated that between 30% and 50% of offenders with child victims were likely to be pedophilic.

Despite the heterogeneity among child molesters, there is also ample empirical evidence to support the hypothesis that sexual age preference is an important discriminator among those who have sexually offended, and offenders against children differ from offenders against adults in multiple important ways. Understanding child molestation requires both a description of their general differences from rapists and a delineation of the heterogeneity within this class of offenders.

Differences Between Child Molesters and Rapists

Substantial empirical data support the differentiation between rapists and child molesters. In addition to their unique erotic age preferences, child molesters are differentiated from rapists on a number of criminological and behavioral characteristics that are relevant to their treatment and dispositions. These include lower social competence, lower aggression in both sexual offenses and general behavior, less psychopathy, less drug and alcohol abuse, more sexual specialization, and less extensive criminal histories. Specific neurodevelopmental perturbations (e.g., low IQ, short height, increased birth complications) also discriminate offenders who are intensely sexually aroused by, or prefer, children from those who assault adults. Finally, recent data from the Massachusetts Treatment Center (MTC) follow-up study found that risk assessment instruments developed to capture the unique attributes of child molesters and rapists may yield more accurate predictions of each group's sexual recidivism.

Differences Among Child Molesters

From the beginning of the psychological and forensic study of offenders with child victims, their heterogeneity has been apparent. The earliest descriptive studies of these offenders focused on speculative systems that attempted to discriminate among purported types. The MTC Child Molester Typology (MTC:CM), now in its fourth version (MTC:CM4), remains the only extensively empirically validated typological system for these offenders. It provides a framework for understanding the differences among child molesters. This typology, which focuses on extrafamilial offenders against children, comprises the overarching dimensions of fixation/social competence and externalization/psychopathy.

Fixation measures the degree to which a child is the focus of the offender's sexual fantasy and behavior, analogous to the sexual arousal to children component in David Finkelhor's four preconditions model of child sexual abuse. *Social competence* assesses the degree to which the offender has negotiated life's social demands and responsibilities, a parallel of the blockage component in the four preconditions model. The confluence of these two independent dimensions yields a group of high-fixated, low socially competent offenders who are high on the neurodevelopmental perturbations cited earlier. In the large MTC sample, neurodevelopmental perturbations were found to be distributed as a *taxon* (a distinct, naturally occurring category of offenders) that was largely populated with high-fixated, low social competence pedophilic child molesters who had a more exclusive sexual focus on children, as opposed to adults. High-fixated, low social competence taxon members were more likely to have male victims and to have offended predominantly against prepubescent children. The categorical distribution of pedophilia has been replicated in a European sample, using self-report and performance-based measures of sexual preferences.

The externalization/psychopathy dimension in the MTC:CM4 model, which is similar to the disinhibition component in four preconditions model, has been found to be independent of fixation but correlated with the social competence dimension such that lower competence is related to higher externalization. In both child molesters and

rapists, aspects of externalization/psychopathic continuum have consistently correlated with hypersexuality, which is unrelated to fixation and sexual preference. Moreover, the externalization continuum has also been found to covary substantially among child molesters with the relationships that offenders have with their victims in nonsexual contexts. This link provides an informative description of variation along the externalizing continuum. Offenders at the low end tend to be pedophiles who seek interpersonal relationships with their victims, spend considerable time with children in nonsexual contexts, are low in their general impulsivity, and low in the amount of physical damage they do to victims. In the middle of this continuum are exploitative, opportunistic offenders who abduct their victims and show moderate amounts of impulsivity. At the high end are sadistic offenders who manifest a synergistic convergence of sex and aggression in their sexual crimes and gain gratification from harming their victims.

Etiological Models of Child Molestation

The major discriminators among child molesters identified in MTC:CM4 also constitute key domains in etiological models that have been proposed for child molestation. In retrospective studies of adolescents who have sexually offended, the convergence of high fixation and low social competence that was identified in MTC:CM4 corresponds to a pedophilic path that covaries with sexual and masculine inadequacy. Seto has referred to this etiological path as the motivational path. The retrospective studies indicate that developmental experiences of emotional and sexual abuse and poor attachment to caregivers are the earliest predictors of this path, and they hypothetically interact with neurodevelopmental perturbations in increasing the likelihood of sexual attraction to children.

A second etiological path has been found to coincide with the MTC:CM4, externalizing/psychopathy domain. Experiences of physical, emotional, and sexual abuse predict higher externalization on this path, which Seto has referred to as the facilitation path. He speculates that the self-regulation and emotional dysregulation problems associated with this path are an

important differentiator between noncontact child pornography users and contact child molesters.

Predictors of Recidivism for Child Molesters

Multiple actuarials and structured clinical guidelines have been generated to evaluate reoffense risk of sexual and nonsexual crimes, but little research has examined their differential predictive power for child molesters and rapists. Analyses of the MTC follow-up database found that the most frequently used risk instruments for predicting subsequent sexual offenses yielded marginal to modest accuracy for child molesters. Items that tapped into a sexual deviance–repetition dimension in the assessed instruments predicted better for child molesters than rapists, and items assessing a criminality–general violence dimension were superior predictors for rapists.

Consistent with these results, Sébastien Brouillette-Alarie and colleagues' analysis of more than 2,500 sex offenders examined the factor structure of the two most frequently used actuarials to assess recidivism risk in sex offenders (Static-99R and Static-2002R). They identified a three-factor solution: (1) persistence/paraphilia, a construct related to sexual criminality, especially of the pedophilic type; (2) youthful stranger aggression, a construct centered on young age and offense seriousness; and (3) general criminality, a construct that reflected the diversity and magnitude of criminal careers. In light of the analyses of the MTC follow-up study, it is likely that the first factor will predict better for child molesters, and the second and third factors will be more accurate for rapists. It is important to note the consistency of these factors with the critical domains found important in the etiological and typological models discussed above.

Assessment and Treatment

Karl Hanson, Guy Bourgon, Leslie Helmus, and Shannon Hodgson demonstrated in 2009 that the three treatment principles (risk, needs, and responsivity) that Don Andrews and James Bonta had established as the cornerstones of effective correctional intervention also applied to the treatment of those who had sexually offended. These principles

prescribe the allocation of treatment resources to those at the highest risk, interventions that target criminogenic needs (i.e., dynamic risk factors associated with the probability of recidivism), and treatment that is individualized to the needs and response styles of offenders.

To prioritize limited agency resources and identify the positive impact on recidivism reduction, the risk, needs, and responsivity treatment model requires the assessment of criminogenic needs prior to intervention and the tracking of the dynamic change of such needs during treatment. In accordance with this model, the treatment of extrafamilial child molesters requires assessing and targeting dynamic factors that have been identified as critical factors in predicting recidivism specifically for them. This includes sexual age preferences, intimacy deficits/emotional congruence with children, sexualization/hypersexuality/paraphilias (found both to predict recidivism and covary with the externalization continuum), and self-regulation/emotional dysregulation difficulties. These dynamic targets for treatment are not only important in predicting recidivism but also play essential roles in the etiology of child molestation and the typological differentiation among those who sexually offend against children.

EXTRAFAMILIAL CHILD MOLESTATION, THEORIES OF

Extrafamilial child molestation is child sexual abuse involving contact between a child and a nonfamily member. Extrafamilial sexual abuse may be categorized as stranger or nonstranger perpetrated. The majority of extrafamilial offenders know their victims. These offenders are often found in roles of authority, volunteered positions, or in nonfamilial caregiver roles. Except for offenders who took vows of celibacy, most offenders are married. Intrafamilial and extrafamilial offenders who know their victims are very similar in psychological factors.

Both offender types are also similar in the number of victim disclosures that occur. Only one third of child molestation survivors disclose their abuse during childhood, and 60% delay disclosing for 5 or more years after the first child molestation episode. Many survivors wait decades before disclosing their abuse, and 20% of survivors never disclose. This may be partly because offenders that know their victims gradually become intrusive and continue offending for long periods of time. Unlike intrafamilial offenders, extrafamilial offenders' roles are not as conducive to penetration of the victims. Therefore, intrafamilial offenders are more likely to complete intercourse with their victim.

Upon suspicion or knowledge of extrafamilial molestation, concordant maternal belief and protective action by the mother is more likely when the mother postponed childbirth until adulthood and the mother is not in a sexual relationship with the offender. Mothers without prior knowledge of their child's sexual abuse are more willing to believe their child's disclosure than mothers aware of previously reported incidents of sexual abuse of their child. However, children demonstrating sexualized behaviors are deemed less reliable by a nonoffending parent and nuclear family. These sexualized acts with other children can taint the child victim's unconscious cry for help and adult intervention. The child victim may not psychologically understand his or her feelings or physically understand his or her body's language for several years. This entry discusses the identification and determinants of extrafamilial child molestation.

Offender Profiles

The largest demographic difference between intrafamilial and extrafamilial offenders is sexual orientation. More extrafamilial offenders report their sexual orientation as nonheterosexual, with higher recidivism rates, as compared to intrafamilial offenders. Research confirms higher rates of recidivism for male extrafamilial child molesters whose victims were boys (35%) compared to intrafamilial child molesters (13%). These men, who were also gender nonconforming in childhood, were noted as significantly more likely to report having a history of child sexual abuse than their gender-conforming counterparts or those of the opposite sex. Although small, the differences between extrafamilial and intrafamilial offender psychological factors exist. Extrafamilial offenders show greater antisocial tendencies and atypical sexual interests. To date, no one factor explains why some people sexually offend against related children versus unrelated children.

Offenders' need for emotional congruence with children is an exaggerated cognitive and emotional need for childhood and children. Emotional attachment and dependency needs are likely met by interactions with children. There is a lack of research exploring offense-related psychological risks associated with emotional congruence with children. Therefore, the following three factors

should be considered for exploratory research only. If sex offenders are blocked from satisfying intimate relationships, they may feel the need to reach out to children as less threatening, and equally desirable, partners. Some sexual deviants, beginning in their adolescent years, are attracted to children and prefer children as intimate partners. Other offenders may have a preoccupation with sex or poor sexual self-regulation, which may co-occur with emotional congruence with children. Extrafamilial offenders typically have greater emotional congruence with children than intrafamilial offenders.

Extrafamilial offenders who know their victims engage in grooming behaviors that often occur over time. Although intrafamilial offenders also engage in grooming behaviors with their victims, their tactics involve more tangible rewards, threats of danger to friends and family, or disbelief by relatives. In contrast, extrafamilial offenders' grooming tactics resemble an adult courtship, anticipating a long-term relationship. The offender's goal is to gain the child's trust so that the child does not disclose the abuse, which most do not. In doing so, the offender's precarious search is over and his or her sexual desires are met. However, when the source of intimacy is lost, the offender will be primed to reoffend and once again use adult-like grooming tactics.

Extrafamilial molestation offenders who are strangers to their victims exhibit very different and distinct behaviors. Stranger offenders show no affection and typically use force on their victims. It is not uncommon for the offenders to kill their child victims. No grooming behavior is involved because the offender does not want the child to become familiar with his or her physical appearance or personality. Such knowledge makes the offender vulnerable to discovery if the child discloses the abuse.

Offenders who selectively target children unknown to them represent a very small minority of child molestation offenders. These offenders are more likely to be antisocial and pedophilic. Offenders perpetrating on children unknown to them typically have higher rates of reoffending than with intrafamilial offenders and extrafamilial offenders who know their victims. Offenders and their unknown victims lack relationships, which has been found to be related to higher rates of

sexual offense recidivism. If both categories of extrafamilial offenders are combined, then the recidivism rates for extrafamilial offenders are 3 times greater than the recidivism rates for intrafamilial molesters.

There are systematic criminal patterns in males convicted of sexual offenses against children. Extrafamilial offenders usually have already committed nonsexual crimes before their first sexual contact with children. They are more prone to relapses into sexual offending than intrafamilial offenders when there is a lack of a relationship between the offender and a child. These offenders also have been found to relapse into violent, rather than sexual, criminality. These sexual offenders have been found to show, after 10 years, reconviction rates of almost three of four, for non-sex offenses.

Crime Theories

The routine activities theory suggests that crime occurs when there is an offender and victim not in the presence of a guardian. This theory emphasized the importance of daily life routines in an offender's life. This is true for extrafamilial offenders working with children on a daily basis, yet there is a gap in the research regarding this influential context when examining child molestation. The crime pattern theory also applies to children of sexual abuse offenders. When an offender is primed and comes into the same spatiotemporal space repeatedly with a child victim, the offender will commit a crime. Previous models and theories exist pertaining to risk-relevant patterns within child molester behaviors. A more recent theory concerning recidivism is based on the four themes of fixation, regression, criminality, and aggression. Fixation and aggression proved to be effective in predicting recidivism.

Fixation involves conscious, explicit planning, along with well-crafted strategies for sexually offending. When explored, fixation was evidenced by the relationship between sexual deviance and persistence of sexual offending. The second theme is *regression*, involving the regressed sexualization of the victim. The offender rationalizes his repeated assaults on the victim. Sexualization is usually in the form of fondling, tickling, and offender gratification. The offender is usually older, has a closer

victim–offender relationship, and has usually cohabitated with a partner during his adult life. The fixation theme typically applies to intrafamilial and extrafamilial offenders who know their victims.

The third theme, *criminality*, describes offenders who abuse children as part of their antisocial behavior. The offender is not fixated on the child victim but on prior and future acts of criminality, specifically rape. The fourth theme, *aggression*, is evidenced in offenders with a history of violence and offending. Signs of aggression and sexualized violence are expected at crime scenes where sexual abuse has occurred. Sadly, most child victims do not survive because of the risk of disclosing and identifying the perpetrator.

Implicit Theories (ITs)

Distorted ITs supply an offender with explanations of events or rationalizations as to why his or her abnormal thoughts are normal, regardless of the reasoning. For obvious reasons, exploratory psychological research into human behavior and cognitive thought processes are central to research involving child sexual abuse. Offenders have distorted beliefs that children want sex, enjoy it, and that it does no harm to them because they are sexual creatures. Differences have not been found between ITs for extrafamilial versus intrafamilial molesters. However, not every researcher or clinician divides extrafamilial molesters into stranger and nonstranger groups. For the purpose of the information presented here, differentiations will be made between the two groups of molesters (extrafamilial and intrafamilial) as well as the subgroup of extrafamilial molesters, stranger molesters.

It is thought that individuals who sexually offend against children experience adverse events during childhood that make them incapable of explaining the events that occurred. Theorists posit that as these children grow older, they develop inappropriate ITs for the adverse events that occurred during their childhood. It is believed the ITs become offenders' framework for explaining, understanding, and anticipating victim's thoughts as well as their desires and beliefs. A classification of six ITs describes the entire range of child molesters' cognitive distortions. These ITs

are as follows: entitlement, nature of harm, uncontrollability, child as sexual being, it is a dangerous world, and child as a partner.

Based on behavioral differences among intrafamilial offenders, extrafamilial offenders, and extrafamilial stranger offenders, the ITs represent some offender types better than others. Because human behavior is unpredictable and involved, there is no set framework or master descriptive that represents all cases. Aggressor types feel entitled and believe they possess a special status that authorizes them to do as they please. Intrafamilial offenders may feel they deserve sexual pleasures because they are head of the household.

Both types of offenders could interpret the nature of harm IT as having sex with a child is not necessarily bad or harmful. They may try to justify their actions based on the child's young age and the chance that the child will never remember the sexual encounters. The uncontrollability IT reflects the idea that offenders are helpless and lack control of their emotions and needs. These offenders may demonstrate this by their willingness to patiently groom a child for sex rather than confront an adult about his or her true feelings and desires. Child as a sexual being, the fourth IT, is interpreted by both types of offenders to mean that children are sexual by nature. Offenders can convince themselves that children are sexually mature and capable of consenting to sexual activity. An incarcerated offender stated in an interview, for example, that his young daughter seduced him because she walked around with her hands in her pants.

Cognitive distortions may seem ludicrous to some, but a child molester interprets a dangerous world IT to be a way to punish those who he or she thinks could or might harm him or her. The victim may be an innocent child, left abandoned and sexually abused, but the offender demonstrated his or her power so that all would know he or she would not be rejected. The last, and more recent IT, is child as a partner. Both types of offenders demonstrate this theory in different ways. For example, an intrafamilial offender may choose to replace his wife, if she becomes distant or withdraws emotionally from him, with his daughter as his intimate partner. An extrafamilial, nonstranger offender may never have felt comfortable around members of the opposite sex yet has

sexual desires and needs. Choosing a child is less threatening and safer for the offender.

EXTRAFAMILIAL CHILD MOLESTATION, TYPOLOGIES OF

Extrafamilial child molestation refers to child sexual abuse that takes place outside the family dynamic. Extrafamilial child molestation or child sexual abuse involves a child being exposed by an adult outside of his or her family to sexual behaviors, such as fondling, intercourse, and oral sex, or other sexual activities, such as viewing pornography. Extrafamilial abusers may be babysitters, neighbors, or family friends. The impact of child sexual abuse can lead to devastating outcomes, such as higher rates of psychological and social distress, cognitive difficulties, emotional imbalances, and suicide. Children often do not understand what is happening and experience high levels of psychological distress, guilt, poor self-esteem, and self-doubt after being molested. For these reasons, child sexual abuse is one of the most unreported sexual crimes. Extrafamilial child molestation may be easier to prevent than intrafamilial child sexual abuse because abusers typically have to go to greater lengths to molest. As such, this entry discusses the etiology and typologies of extrafamilial child molesters.

Etiology

Child sexual offenders are dissimilar in their characteristics, coming from a wide variety of backgrounds and demographics. It has been found, however, that offenders are more likely to have experienced caregiver inconstancy, a highly correlated predictor of sexual violence in adults, which causes attachment disorders. An estimated 93% of all child molesters have displayed an insecure attachment, which leads to difficulties coping,

interpersonal deficits, and low self-esteem. Research also indicates that child molesters are also more likely than nonoffenders to have been victims of sexual and physical abuse at a young age. In comparison, rapists and child sexual molesters have earlier onsets of heightened sexual experience, such as exposure to pornography, sexual experience involving animals, higher prevalence of child sexual abuse, and earlier onset of masturbation. It is thought that these types of psychosocial shortcomings and past history of sexual abuse may cause individuals to be unable to have healthy adult relationships and thus turn to children to fulfill their sexual needs.

Pedophilic and Nonpedophilic Distinction

Child sexual molesters are distinguished by either being pedophilic or nonpedophilic in nature. Extrafamilial child sexual abusers are more likely to be diagnosed with pedophilia than intrafamilial abusers. Pedophilia is described as being sexually attracted to children, which may or may not lead to child sexual abuse. According to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, pedophilic disorder is defined by a person who is at least 16 years old, having reoccurring, intensely arousing sexual urges, fantasies, or behaviors involving sexual activity with prepubescent children, for 6 months or longer. The individual has either acted on these experiences or feels great distress or interpersonal difficulty due to these urges. Acting on these sexual urges does not necessarily mean molesting a child; for example, it can include masturbation involving fantasies with children or viewing child pornography. Other specifiers include exclusive type (attracted only to children), nonexclusive type, sexually attracted to males, sexually attracted to females, sexually attracted to both, and limited to incest.

Individuals diagnosed with pedophilia are typically single males who demonstrate poor social competence, have low self-esteem, and have a comorbid antisocial or narcissistic personality disorder. They often go out of their way to be involved with children by having occupations involving children or have childlike hobbies. They typically have lower IQs, difficulties with processing speed, and have higher rates of being

left-handed than nonpedophilic controls. Individuals diagnosed with pedophilia are more likely than those who are not diagnosed with this disorder to have multiple victims. They are also prone to recidivism.

Groth's Fixated Versus Regressed Subtype

Another distinction of the different types of child sexual abusers is known as the fixated-regressed subtype. In 1982, A. Nicholas Groth and colleagues developed this dichotomy based on how deeply the deviant sexual behavior is rooted and the underlying reason for psychological need. Fixated child molesters do not have healthy adult sexual relationships and are sexually preoccupied with, and prefer, children. Their victims are extrafamilial and are often vulnerable children who are lonely or somewhat neglected. Their offenses are premeditated and often involve long periods of grooming. *Grooming* is the process in which child sexual abusers gain their victim's and caregiver's trust and isolate the child in order to create secrecy around the sexual abuse and relationship. Fixated offenders' motivation to molest is not stimulated by stress and often begins during adolescence.

Those of the regressed subtype have normal sexual adult relationships and tend to molest during stressful periods of times as a coping mechanism. The behavior emerges in adulthood and is accompanied by periods of low self-esteem and poor self-confidence. Regressed offenders are not pedophilic per se, unlike their fixated counterparts. Fixated abusers are more likely to have male victims, have psychopathic traits, and be more violent to their victims. They are also more likely to have multiple victims and high rates of recidivism. Regressed offenders have lower rates of reoffending and are more remorseful for their crimes.

The Federal Bureau of Investigation (FBI)'s Typologies

The United States FBI expanded upon Groth's *fixated* and *regressed* typologies and developed five additional subtypes. These are morally indiscriminate, sexually indiscriminate, inadequate, seductive, and sadistic.

The regressed, morally indiscriminate, sexually indiscriminate, and inadequate typologies are situational offenders who molest when their environment permits or encourages these behaviors. According to the FBI's typologies, *regressed* offenders target easily accessible children as a substitute for adult sexual contact. This type of offender demonstrates poor social skills. The *morally indiscriminate* subtype are offenders who do not have a preference for children but use child victims to fulfill their own interests and/or sexual needs if they are easily accessible. These offenders may also victimize adults as well. *Sexually indiscriminate* offenders are most interested in sexual experimentation and molest children out of boredom. *Inadequate* offenders are social outsiders who demonstrate low self-esteem and view molesting children as their only sexual outlet.

The seductive, fixated, and sadistic offenders prefer to victimize children. *Seductive* child sexual offenders use intensive grooming to keep a long-term relationship with their victims. They will give the child gifts, love, enticements, and affection to maintain the secrecy and stability of the relationship. *Fixated* offenders experience deficiencies in their psychosexual development and remain compulsively attracted to children throughout their adulthood. This subtype is the most pedophilic in nature. Of all the FBI's subtypes, the *sadistic* offenders are the most dangerous. Violence and aggression excite them. These offenders even target stranger victims. Although these typologies can be applied to both extrafamilial and intrafamilial sexual molesters, it is more likely these preferential offenders will have extrafamilial victims. Situational offenders tend to molest children that are easily accessible, such as family members.

EXTREMISM AND TERRORISM, MIDDLE EASTERN

The simplest definition of *terrorism* is the deliberate use of violence against civilians to achieve political goals. *Extremism* refers to political ideologies that are inconsistent with, or in conflict with, a society's core values and principles. Basic elements of terrorism include that it is calculated (e.g., requiring time, planning, organization), involves violence against noncombatants, and is intended to shock. The purpose of terrorism is to create a high-profile impact with horrifying consequences, publicize a political or religious cause, intimidate and coerce authorities to accept demands, and undermine public confidence in their governments. This entry discusses modern religious extremism and terrorism originating from the Middle East.

The best known terrorist groups are al-Qaeda and the Islamic State of Iraq and Syria. Al-Qaeda committed the September 11, 2001, series of four coordinated terrorist attacks against the United States that killed 2,996 people, injured over 6,000 others, and caused at least US\$10 billion in infrastructure and property damage. Islamic State of Iraq and Syria caused, and is still causing,

destruction in Iraq and Syria that has resulted in thousands killed and injured, along with millions of individuals dislocated and towns destroyed.

Political Justification

The goal of Middle Eastern extremists and terrorist organizations is to politicize religion, gain control, and govern. They want to establish government rule by Sharia (i.e., Islamic) law. There is a vast array of purported root causes for the surge of extremism and terrorism in Middle Eastern countries. These include:

- undemocratic political and repressive political environments,
- disproportionate distribution of extreme wealth emanating from oil,
- decline of the Middle Eastern world into a marginalized region,
- perception of an immense discrepancy between the rich West and most Middle Eastern countries,
- histories of occupation,
- conflict between Israel and the Arab world,
- use of religion by ruling governments to fight communism and other political opponents,
- the Soviet invasion of Afghanistan,
- U.S. troop presence in Saudi Arabia during the Gulf war,
- the United States' 2003 invasion of Iraq,
- wealthy Arab countries controlling the political agenda through religion in the region and exporting their extreme religious ideologies and teachings around the world,
- the Iranian revolution's extensive use of religious rhetoric,
- the unequal distribution of power,
- unrepresentativeness,
- government inefficiency and corruption, and
- enormous police and military power.

Social Justification

Social causes for the surge of extremism in Middle Eastern countries include poverty, economic discrepancy between the rich and the poor, the general economic decline, high unemployment, the sense of being disenfranchised from community, a culture of hopelessness and ineffectuality, and the

tremendous population increase. These things can lead to feelings of deprivation, frustration, and injustice. The prevalent sociological reason given for extremism in the West is that homegrown extremists and terrorists are the result of failed integration policies, alienation in their adopted countries, and hatred for Western values.

Psychological Justification

Several psychologically based theories have been suggested to explain the phenomenon of Middle Eastern extremism and terrorism. They are briefly presented below.

Personality Traits

Some suggest that extremists and terrorists suffer from a disturbed relationship with their own identity, an inferiority complex, a lack of sense of independence, low self-esteem, and an absence of empathy, as well as potentially having injured narcissism, paranoid tendencies, and a preoccupation with power. Others have argued that terrorists emerge out of a normal psychology of emotional commitment to a cause. They are rigidly devout. They get involved in terrorist acts because it provides them with a sense of identity, camaraderie, self-actualization, fulfillment, status, power and direction to their lives, and fame.

Thinking

Extremist thinking is described as rigid, primitive, unsophisticated, and an oversimplification of complex issues. It results in a dichotomized world that divides issues and persons into only states of right or wrong, good or evil, rich or poor. This thinking is built on the rejection of others' views and imposition of their views on others. Extremists' and terrorists' actions are based on a subjective interpretation of the world rather than objective reality. They are utopian in their thinking, and they compare existing, flawed systems against their own *perfect* ideology.

Emotions

Extremists and terrorists are sometimes described as filled with negative feelings/emotions. These include feelings of disappointment,

frustration, fear, disgust, anger, and hatred toward all other faiths, unobservant and corrupt leadership, and whoever disagrees with their views. Extremists' and terrorists' feelings of dissatisfaction may stem from failures in their personal lives, for example, the inability to hold a job, rejection by the military, failed marriage, addiction, inability to adjust to modernity, discontent with some personal needs or objectives, and dissatisfaction about one or a combination of existing social, economic, political, cultural, or religious conditions. Importantly, they perceive themselves and their group as victims of injustice with no conventional hope for success.

Negative feelings that promote extremism have been cited among some immigrants from Middle Eastern countries to Western countries. These include feelings of being excluded and discriminated against because of their faith, rejection of Western culture and carry over hatred for Western values, the overwhelming experience of adapting to a new country, and feelings that modernization put them in a worse moral situation than they experienced previously.

Negative emotions are not the only emotions that inspire extremism. Other causes for joining a terrorist organization include the need for excitement and adventure, the feeling of being powerful, and a sense of belonging to a close network.

Belief System

Religious belief is the greatest motivating factor for extremists to become involved in terrorist activity. They do not believe in nonviolence or political solutions but want to wage *jihad* (holy war). They believe they are serving the ultimate religious cause and that their beliefs are superior to others' beliefs. For these individuals, the terrorist actions represent the execution of the will of God. They believe that fire and punishment are reserved for infidels and paradise is reserved for the faithful and that they are in a war between believers and corrupt, apostate regimes. They believe it is the duty of their coreligionists to struggle to build and maintain a righteous community and fight ungodly rulers, and that adherence to the purity of their religious practice is the road to salvation. There is the concern that Western culture will overwhelm their culture and is

trying to undermine them, and that their countries are the target of attacks by Christian Europeans. They believe that their countries have decayed because they have strayed from their religion and deserted *jihad* and that their religion is the only permissible religion, to which all others must yield. They see themselves as noble, morally superior liberators, martyrs, and legitimate fighters for a just social cause. Sacrificing their lives for God is considered an honor, with martyrdom the highest religious devotion and martyrs receiving extraordinary rewards for their fight and sacrifices, including going to the Garden of Eden and enjoying unlimited sexual pleasures.

Attitudes

Extremists teach children from a young age that they must stay away from unbelievers, idolaters, and foreigners (especially Westerners) and that the West is a source of evil. This attitude of rejecting the Western culture is particularly central to the extremist movement. Those Westerners around them are considered racially and culturally inferior, immoral, and materialistic.

Attribution

Extremists and terrorists justify their behavior by denying that they are causing harm to others and gaining benefits for themselves. They displace responsibility and externalize the blame to others, believing that they are victims. They also dehumanize their victims.

Cognitive and Emotional Dissonance

Extremists and terrorists are caught between a culture that goes back 1,400 years and modernization. This can result in anxiety, alienation, rigid beliefs, and inferiority complexes. Many immigrants to the West believe that they can lead a successful life and educate their children while shielding themselves and their families from any immoral Western cultural influence. Parents regularly teach religious commitment and other values from their original culture. School and the culture, however, have a more secular approach (or at least less commitment to religion) with different, and often conflicting, values. This can lead to psychological stress and dissonance.

Conformity

Peer pressure, group solidarity, and the psychology of group dynamics help members remain in terrorist and extremist groups. People tend to submerge their own identities into the group, resulting in a kind of group mind and identity. It can also result in a group moral code that requires unquestioned obedience to the group.

Brainwashing

Extremist and terrorist groups brainwash their members with their particular ideology. Brainwashing occurs by overwhelming the individual's mind prior to him or her becoming a terrorist. Victims of brainwashing are bombarded with one-sided views and beliefs that are conducive to them becoming terrorists. Groups implant their views in school, the media, and extremists' religious sermons.

Biopsychosocial Theories

Biopsychosocial theories suggest a link between aggression and unbalanced levels of chemicals in the brain (e.g., serotonin, dopamine), unbalanced hormone levels, and frontal lobe problems.

For example, some studies have reported a relationship between lower levels of serotonin and higher levels of aggression in humans. A relationship has also been identified between dysfunction or impairment in the prefrontal cortex of the frontal lobe and antisocial and aggressive behavior, particularly among the offender population.

Extremism and Mental Illness

Some have suggested that the behavior of terrorists can be explained by mental illnesses, such as psychotic states, psychopathy, narcissism, schizophrenia, paranoia, depression, and borderline or passive-aggressive personality disorders. However, investigations and interviews with terrorists and their relatives from different countries have not found evidence of mental illness or psychological abnormalities, at least not in regard to modern psychiatric nomenclature.

Extremism and Criminality

Extremists and terrorist organizations kill with the goal of terrorizing others; steal; force

organizations, business, and ordinary citizens to pay protection money; and kidnap for the purpose of negotiating ransoms to finance their operations. Although these actions are criminal, many of these individuals have no prior criminal history. Some, however, have been involved in petty crimes such as forgery, credit card fraud, and marijuana dealing.

Radicalization and Recruiting in Prisons

Radical Islamic views are preached in Western prisons and have been known to successfully convert certain offenders to radical Islam. Prisons represent ideal and fertile environments for radicalization because the prisons constitute violent, isolated environments; a captive audience; the absence of day-to-day distractions; and a group of angry, resentful, and disaffected young men. Some offenders join radical groups for protection or status among other prisoners. Offenders often share similar socioeconomic demographics and disaffected psychological characteristics with terrorists. These characteristics include youth, unemployment, alienation, the need for a sense of self-importance, and the need to belong to a group. Offenders are also vulnerable to radical religious ideology due to antisocial attitudes and the need to identify with other inmates sharing the same background, beliefs, or ethnicity. Factors that add to the increasing vulnerabilities include a high level of distress, cultural disillusionment, lack of preexisting or intrinsic religious beliefs or values, and dependent personality tendencies.

Assessment Measures

The risk/needs assessment tools commonly used to assess violent offenders are not suitable to assess extremists/terrorists. For example, the Level of Service Inventory, the Violent Risk Assessment Guide, and the Self-Appraisal Questionnaire were not designed or standardized for use with terrorist offenders. Their reliability and validity for use with extremists and terrorists have not been demonstrated.

Assessment and Treatment of Radicalization Scale (ATRS)

Because common assessment tools are unsuitable for assessing terrorists, a new measure was

developed to specifically to measure Middle Eastern extremism/terrorism. The ATRS, formerly the Belief Diversity Scale, was developed to canvas topics commonly reported in the literature as being indicative of, and/or related to, Middle Eastern ideologies that are the basis of extremism.

The ATRS consists of seven subscales, each designed to focus on a prominent ideological theme. The first subscale reflects negative attitudes toward Israel. The second subscale, titled Political Views, measures the important political views Middle Eastern extremists advocate (e.g., opposing secular laws and governments, and advocating for the implementation of the Sharia Law). The third assesses participants' attitudes toward women. These current, extreme attitudes are mainly repressive and represent extremists' views of the inferior role of women in society. The fourth subscale measures negative attitudes toward Western culture. Middle Eastern extremists have been vocal in their rejection of Western culture, claiming that Western civilization is corrupt and that the West is trying to undermine their religion. The fifth subscale, Religiosity, assesses respondents' commitment to their religion. Some questions in this subscale tap into extreme religious views that are common in the Middle East. The sixth subscale, Condoning Fighting, measures views that condone fighting and promote acts of violence as a means for the revival of religion, with the goal of destroying infidels (i.e., atheists and nonbelievers in Islam) and achieving a world with only one religion (Islam). The seventh and final subscale is a validity scale that indicates whether participants misunderstood the items, answered carelessly, or deliberately attempted to conceal their true answers.

The Violent Extremism Risk Assessment (VERA)

The VERA tool is designed for use with persons who have a history of extremist violence or have been convicted of such offences. To complete this measure, professionals must use the structured professional judgment (SPJ) schema. Using the format and structure of traditional SPJ tools, the VERA guides the assessor to consider and score risk factors (e.g., low, moderate, and high risk)

identified in the literature as relevant. The Attitudinal section of the VERA comprises items assessing an individual's attachment to ideology, perception of injustice, perception of target, identity issues, and empathy. Contextual items guide the assessor to consider the individual's social environment. Historical items look to factors associated with exposure to violence, violence training, and glorification of violent action. The fourth category guides the evaluator to seek out information that could serve as protective for the individual. As with other SPJ tools, rehabilitation efforts focus on dynamic or changing factors while strengthening protective factors.

There is some measure of overlap between the ATRS and VERA. The ATRS comprises a greater inventory of questions designed to assess fundamentalist and extremist Islamic beliefs associated with ideologically based violence. The VERA is a more traditional SPJ risk tool in style and has more specific items related to associations with violence in the person's background and sense of feeling aggrieved.

Homegrown and Lone Wolf Terrorism

Homegrown terrorists are individuals who were not born in a Muslim country but who joined extremist or terrorist groups while living in a non-Muslim country. Planned preempted or completed terrorist acts in Western countries can be conducted by first- or second-generation immigrants who retained their ideologies or by individuals who have converted to Islam. *Lone wolf* extremists are those who conduct terrorist acts on their own, sometimes under the guidance or direction of an organized terrorist group. They typically believe in the terrorist group ideologies, such as those from al Qaeda or Islamic State of Iraq and Syria leadership.

One reason for the homegrown and lone wolf terrorist phenomenon is that, since the 1960s, dangerous and extremist individuals have been allowed to immigrate to Western countries, where they maintained their extremist ideologies. Another reason is that some individuals who were not extremists when they immigrated then experienced what they perceived as social exclusion, prejudice, and discrimination, making it difficult for them to assimilate into the new culture. This can render them susceptible to extremist and

terrorist recruiters. The powerful effect of extremist ideology and the strong pull of individuals' religious roots sometimes supersede the assimilation process, and then hard-line views are passed to the next generation. Additionally, individuals who are frustrated with their lives or with politics seek others who have similar frustrations. This might lead them to form social networks that may arrive at a decision to commit a terrorist act.

surrounding a witnessed crime as well as identification of participating offenders. Frequently, eyewitness testimony is the most compelling source of evidence in criminal trials and may be the only evidentiary support that links a suspect to the crime committed. Research shows that statements presented by eyewitnesses are influenced by a number of different factors that extend beyond the mere recollection of the event. This is of particular relevance given that inaccurate eyewitness testimony is the leading cause of false convictions in the United States. This entry introduces the role of eyewitness testimony in criminal cases, discusses variables that can influence the accuracy of eyewitness testimony, and reviews both current and proposed methods for mitigating potential biases that arise.

Role and Influence in Criminal Cases

Eyewitness testimony remains an important source of evidence in many criminal cases, even with the availability of more technologically advanced sources such as forensic DNA testing. This is in large part due to the wider availability of eyewitness testimony over sources of DNA when gathering evidence in criminal cases. Still, the technological advances in forensic DNA testing have helped to inform the role and limitations of eyewitness testimony, notably in the exoneration of persons convicted of crimes whose innocence is ultimately demonstrated through DNA analysis, a technology that was not widely available in the recent past. The Innocence Project website has documented 344 such cases, with inaccurate eyewitness testimony influencing over 70% of these wrongful convictions. Indeed, errors in eyewitness testimony remain the number one cause of wrongful convictions, with an estimated one third of eyewitnesses making an inaccurate identification.

Inherent in establishing eyewitness testimony as the leading cause of wrongful convictions is the court's reliance on inaccurate evidence in rendering a verdict, which is influenced by a number of factors. First, judges may have limited understanding of the factors that influence eyewitness testimony and frequently also misjudge the knowledge that jurors may have on the subject. This in turn limits the utilization of an eyewitness expert and prevents the orientation of jurors to the factors

EYEWITNESS TESTIMONY

Eyewitness testimony refers to the report of an event provided by someone who observed this event and often involves the recollection of details

that influence the accuracy of eyewitness testimony. This gap in knowledge surrounding eyewitness testimony may prevent the court from making an accurate assessment of a witness's statement. Indeed, eyewitness confidence, a poor predictor of eyewitness accuracy, is often emphasized over other factors.

Factors Influencing Eyewitness Testimony

There are multiple factors that influence the accuracy of an eyewitness statement. First, one should consider the complex process of memory formation. With very few exceptions, individuals are unable to register and recall an event with the precision and accuracy of a recording device. In fact, memory formation and recall consist of multiple stages recognized to be dynamic, malleable, and susceptible to influence. *Perception*, the observation of an event, can be biased based on the particular aspects to which an individual pays attention. *Encoding*, the transfer of the observed event into a memory, can be subject to interpretation as well as biases that are intrinsic (e.g., knowledge base, prior experiences) or extrinsic (e.g., the presence of a weapon or a disguise) to the individual. *Storage* refers to the preservation of the encoded memory and is susceptible to both modification and deterioration over time. *Retrieval* represents the recreation of a memory, which is vulnerable to unconscious modifications in order to fill in gaps that may be present in the encoded memory.

Other factors that influence the accuracy of eyewitness testimony can be divided into two broad categories. *System variables* refer to factors that affect eyewitness testimony and are controlled by the criminal justice system. Conversely, *estimator variables* are factors that are inherent within the witnessed event. The criminal justice system can estimate the significance in relation to eyewitness testimony, but estimator variables are beyond its direct control. Taken collectively, estimator and system variables may contribute to an erroneous identification of a suspect, with an effect that is likely additive.

Estimator Variables

Characteristics of the witness prior to observing the event in question are an important

consideration when evaluating the accuracy of eyewitness testimony. Among these characteristics are an eyewitness's age, with children less than 10 years of age and individuals more than 70 years more likely to make erroneous identifications than the general population. Additionally, individuals tend to have less accurate facial recognition with suspects who are outside of their own ethnic group, a phenomenon described as the own group bias or cross-race effect. In the same vein, an individual tends to recognize faces with familiar physical characteristics, which can erroneously influence an eyewitness's identification if that individual mistakes the context of this person's familiarity and wrongfully associates it with the memory of the perpetrator.

Other estimator variables that should be considered include characteristics of the event in question as well as the mental state of the witness during said event. For example, the distance between the witness and perpetrator is inversely correlated to an accurate identification. Similarly, lower levels of illumination and shorter exposure to the facial features of the perpetrator are also inversely correlated. Additionally, if perpetrators wore disguises or changed their appearance by altering their head or facial hair, a witness may struggle with an accurate identification.

If drugs or alcohol clouded the sensorium of a witness at the time of the event, the ability to make an accurate identification may be impaired. These effects have been demonstrated specifically for alcohol and marijuana intoxication. A final consideration that can influence eyewitness accuracy is the perceived stress of the event in question. When the perceived threat is minor, the associated stress may enhance one's memory of the event and alleged perpetrator. Conversely, situations that are perceived as highly threatening activate the fight-or-flight response in a witness, which may impair recognition and recall. This is particularly relevant when the perpetrator wields a weapon and potentially impairs a witness's memory, a phenomenon described as the weapon focus effect.

System Variables

An inherent concept of system variables is that they occur following the alleged event. They

include both eyewitness interviews and suspect identification by lineup conducted by law enforcement officers, both of which have the potential to introduce bias if not conducted optimally. For example, interviews conducted during an investigation frequently rely on close-ended questions, which not only may limit the amount of information gleaned from an eyewitness but also have the potential to unknowingly introduce bias given the suggestive nature of some close-ended questions. Additionally, the content provided by an eyewitness during an interview can be influenced by exposure to additional information regarding the event received from other individuals, the news media, or even law enforcement. As memory formation and maintenance are malleable, such postevent information may unknowingly influence what the witness recalls.

The process whereby a witness identifies an alleged suspect is typically a lineup conducted by law enforcement, which has the potential to introduce bias in multiple ways. For instance, the number of individuals participating in a lineup affects the fairness of suspect identification. An insufficient number of participants increases the likelihood that a suspect will be selected by random chance rather than by accurate identification. Similarly, the composition of the lineup may also sway the eyewitness. For this reason, a suspect should not be obviously distinct from other participants in terms of appearance, attire, and physical positioning in relation to the eyewitness.

The verbal interactions between an eyewitness and law enforcement immediately before and after the lineup can also constitute a source of bias. Specifically, if a witness is not advised that the alleged perpetrator may not be present in the current lineup, then that witness has a significantly higher chance of making a false identification. The *relative judgment process* refers to the tendency of a witness to identify the person who most closely resembles the perpetrator when the actual perpetrator is not present within the lineup. The risk of making an erroneous identification based on similarities in appearance can be minimized by a *pre-lineup admonition* as described earlier. An additional consideration involves law enforcement's response when a witness identifies the suspect within the lineup. If officers confirm that the suspect was correctly identified, the witness's

confidence that the suspect is the actual perpetrator may be bolstered. The *postidentification feedback effect* refers to the augmentation of a witness's memory due to a newfound confidence that the perpetrator was correctly identified. This may have a significant impact, given that confidence is often regarded by the court as a predictor of accuracy in eyewitness testimony.

Methods to Mitigate Inaccurate Testimony

A standard measure of evaluation exists that functions to ensure eyewitness testimony is sufficiently reliable for inclusion into evidence. Modifications to this standard have been proposed that seek to more stringently evaluate for accuracy, recognizing that any degree of suggestibility is a form of bias that can negatively impact the veracity of eyewitness testimony.

Current Standard

Although states may vary slightly in this regard, the national standard for assessing reliability of eyewitness testimony is based on the 1977 decision of the Supreme Court of the United States in *Manson v. Brathwaite* (1977). Referred to as the *Manson test*, this standard involves consideration of two aspects of eyewitness testimony. First is an evaluation of whether the procedure surrounding the identification of the alleged witness was unnecessarily suggestive. Close attention is paid to (1) the presentation of the alleged suspect during the lineup, (2) whether a pre-lineup admonition was administered, and (3) the presence of any confirmatory statements made by law enforcement once the suspect was identified. If there is no evidence of suggestibility, then the testimony is admitted into evidence.

On the other hand, if there is evidence of suggestibility, then five additional criteria are used to assess the reliability of the testimony. These include (1) the extent to which the witness was able to observe the alleged perpetrator, (2) the attention paid by the witness during the event, (3) the confidence of the witness at time of identification, (4) the degree to which the description provided by the witness matches the appearance of the suspect, and (5) the time between the event and the identification.

Considering such additional notions seems reasonable when suggestibility is evident; however, it is important to note that the first three criteria (observation, attention, and confidence) are subjective, relying purely on witness self-report, with confidence being particularly problematic in this regard. Furthermore, the accuracy of witness descriptions has been shown to lack significant correlation to reliability. Finally, although the time that lapsed between the event and the identification is correlated to the strength of a memory, the greatest degree of memory attenuation occurs within minutes of the event. Accordingly, there may not be a meaningful difference in memory strength when the event extends beyond even 24 hr.

Proposed Modifications

A proposed standard for assessing the accuracy of eyewitness testimony is the four-step *I-I-Eye* method, which has been demonstrated to increase significantly the sensitivity of judges and jurors alike to these important issues. Inherent in this method is considering eyewitness testimony as a type of trace evidence, like DNA and fingerprints. With trace evidence, judges determine if appropriate, scientifically based protocols were followed prior to the material being admitted into evidence. The following four steps comprise a proposed protocol for judges to employ in making this determination.

First, one should determine if the interview was optimally conducted by law enforcement by (1) maximizing the amount of information obtained from an eyewitness, (2) not providing postevent information that may bias the recollection of the event, and (3) avoiding confirmatory statements that may increase an eyewitness's confidence. Second, one should assess the fairness of the identification procedures employed. Third, one should identify and consider any estimator variables that may affect subsequent testimony. Finally, conclusions should be based on the following four questions:

1. Did law enforcement obtain the maximum amount of information from the witness?
2. Prior to taking a statement on the confidence of the eyewitness, was any feedback given that may have increased confidence?
3. Is there a low, medium, or high probability that the testimony is accurate?
4. Is there a low, medium, or high probability that the identification is accurate?

A final implication of this proposed standard is its emphasis on how suggestibility may decisively influence eyewitness testimony. Specifically, if bias has occurred during either the interview step or the identification step, it cannot be undone, even if those steps are subsequently repeated. In such instances, with few exceptions, the testimony would be deemed unreliable and would not be admitted into evidence.

FAITH-BASED INITIATIVES

Faith-based initiatives refer broadly to a wide range of interventions and services offered to offenders, victims, and families by volunteers and organizations motivated by religious convictions. Although the term *faith-based initiative* has been associated with the White House Office of Faith-Based and Community Initiatives (now the Office of Faith-Based and Neighborhood Partnerships) since its establishment in 2001, the concept of faith-based initiatives far predates and transcends this federal program. This entry outlines the origin of faith-based initiatives within the criminal justice system, introduces contemporary faith-based programs, and surveys challenges confronting these services.

Origins of Faith-Based Correctional Programs

Faith-based initiatives in the U.S. criminal justice system date to the late 18th century. Religious leaders concerned by the brutality of corporal punishments advocated correctional reforms that gave rise to the penitentiary movement. This movement drew upon the principles and practices of religious monasticism, including silence, solitude, labor, and instruction to reenvision prisons and jails, formerly reserved for pretrial detention and debtors' incarceration, as places of penitence, reform, and rehabilitation for criminal offenders. The first U.S. penitentiaries included

Philadelphia's Walnut Street Jail and New York prisons Newgate, Auburn, and Sing Sing. From its inception, the penitentiary movement was fraught with conflict between religious reformers and security over access and program implementation. Religiously motivated emphasis on rehabilitation waned while incarceration endured as the default criminal punishment in the United States. The penitentiary label is a vestige of its religious roots.

Contemporary Faith-Based Services

Since the 1970s, faith-based initiatives addressing crime have returned to prominence. Programs include prevention efforts, custodial programs, and postrelease services. Community-organizing endeavors like Boston, Massachusetts's TenPoint Coalition and Milwaukee, Wisconsin's Violence-Free Zone Initiative cultivate partnerships between congregations and other community assets, including schools and law enforcement, to curtail gang activity and substance abuse, particularly among youth. Mentorship programs pair at-risk youth, especially children of incarcerated parents, with positive role models to disrupt intergenerational criminal cycles.

Other initiatives mobilize faith-motivated staff and volunteers to serve incarcerated offenders. These interventions range from worship services and scripture studies led by volunteers from local congregations to formal curricula, accredited degree programs, and faith-based dorms and entire prison units operated by contract with state

and federal agencies. The largest organizational service providers include Prison Fellowship, Kairos Prison Ministry, and the Salvation Army, all of which operate internationally. These groups provide visitation, mentorship, life skills courses, substance abuse counseling, and parenting seminars. More extensive academic programs offer bachelor's degrees at no cost to prisoners through partner seminaries. Still other programs offer direct services to inmates' families, including counseling, assistance with visitation processes, and material aid.

Prison Fellowship's most intensive program, the InnerChange Freedom Initiative, bridges in-prison rehabilitation and postrelease aftercare. The InnerChange Freedom Initiative delivers a biblical curriculum within an environment dedicated to its program. It then continues to support participants for up to a year after parole, significantly reducing recidivism. Another innovative initiative bridging prison and parole is the Prison Entrepreneurship Program. The Prison Entrepreneurship Program combines character assessment and development with a business plan competition that challenges participants to cultivate business skills needed upon release. The program also offers transitional housing and continuing education to support reentry.

Still other initiatives focus exclusively on reentry. Religiously operated halfway houses offer safe, stable, and supervised residences to parolees. These residences often offer on-site job skills and technology training, employment and transportation assistance, and ongoing substance abuse counseling. Faith-motivated individuals and organizations help parolees navigate the most vulnerable months of their transition and reintegrate as prosocial community members.

Challenges to Faith-Based Initiatives

Assessing the efficacy of faith-based programs has proven difficult, although the most extensive literature review to date identified positive correlations between religion and crime reduction in 90% of studies. The first hurdle for assessing faith-based initiatives is their sheer diversity. Crime prevention initiatives, victim services, and interventions with offenders both during and after custody defy easy categorization. The diverse

settings for such services virtually ensure some degree of inconsistency in implementation. Different initiatives also claim different outcome measures as appropriate to their respective programs. Recidivism reduction, desistance, institutional conduct, and subjective coping might all be plausible outcome measures for a given initiative, but differing stakeholders may well disagree about which ones are most appropriate. Finally, faith-based initiatives inherently introduce a measure of selection bias since they must be voluntary to protect participants' religious freedom. Careful evaluation design can mitigate this assessment challenge but likely never dispel it entirely.

Mention of religious freedom leads to the second major challenge to faith-based initiatives: questions of constitutionality. Some object to the direction of public funds to faith-based services, even when carefully earmarked for secular aims. Others object to the provision of faith-based services at all, regardless of funding. They contend that religious programs within correctional contexts inescapably privilege one faith over another (or none) and thereby unconstitutionally incentivize religious participation. Concerns to resist government establishment of religion come into tension with protection of offenders' free exercise rights and controversies that have beset faith-based initiatives since the penitentiary's origins reemerge.

FAMILIES OF INCARCERATED OFFENDERS

Based on data from the late 2000s, just over half (52%) of state and under two thirds (63%) of federal inmates in the United States have a minor child. This translates to approximately 1.7 million children being separated from their parents due to incarceration. Additionally, 7% of children in the United States will experience parental incarceration before turning 18 years old. Not all families, however, are equally affected by incarceration. Incarceration is concentrated among individuals of color, African Americans and Latinos in particular, and those of lower socioeconomic standing. Black children are 3 times more likely than White children to have an incarcerated mother. Similarly, among children born in the 1990s, 25% of Black children will experience parental incarceration, compared to approximately 4% of White children. Therefore, the families most likely to experience incarceration are those who are also experiencing cumulative economic, social, and racial disadvantage. Parental incarceration can exacerbate such disadvantage by removing a significant source of income from families. For example, data on state prisons from the late 2000s illustrate that approximately half of incarcerated parents were their families' primary financial provider. This entry focuses on how incarceration affects offenders' relationships with their family members, with a particular emphasis on offenders' relationships with their children and other immediate family members. First, this entry explores how family relationships and parenting are impacted during incarceration, and second, it examines the role of family relationships during offender reintegration.

Incarceration and Family Relationships

Incarceration creates an involuntary separation, both physical and emotional, between offenders and their family members. This leads to significant changes in family relationships and roles. In the case of parental incarceration, often the first change experienced by families is a change in the children's residence, particularly when mothers are incarcerated. Most mothers were residing with their children and were their primary caregivers and sources of financial support prior to incarceration. Following maternal incarceration, children are mostly likely to be cared for by maternal grandparents, which means that maternal incarceration often results in children moving to a new home. Although just under half (42%) of incarcerated fathers were living with at least one child prior to being incarcerated, those who were not coresiding with their children were often providing financial support and caregiving. After fathers are incarcerated, children most often remain in the care of their biological mothers. Therefore, parental, compared to maternal, incarceration may not lead to the same residential instability for children. However, it can result in increased economic strain.

Incarceration also affects the quality of family relationships, particularly parent–child relationships. Incarceration forces families to consider how they will communicate (or not communicate) from significant physical and emotional distances. These distances preclude offenders from participating in the types of activities (e.g., shared leisure, vacations, and family rituals) commonly used to build and sustain family relationships. Without these relationship-building activities, offenders feel as though the quality of their family relationships erodes. Some offenders, particularly fathers, may also attempt to create distance from their families. For example, they may refuse or discourage in-person visits and other forms of contact as well as show fewer emotions when they do communicate with family members. Scholars have suggested that this distancing may be due to offenders' desires to protect their families from the difficulties of the prison context (e.g., challenges in getting to facilities, chaotic visiting environments, and other offenders). Distancing may also allow offenders to avoid emotional pain that may arise

when they see or hear from family members. Contact during incarceration may lead to reliving the process of arrest and confinement. Offenders also express feelings of shame and regret at their family members having to see them incarcerated. Thus by distancing themselves from their families, offenders can simplify the experience of *doing time*.

The ties between incarcerated fathers and their children may be particularly fragile, and it is typically the quality of their relationships with children's mothers that determines the contact incarcerated fathers have with their children. This process is commonly referred to as *maternal gatekeeping*. Results from qualitative studies suggest that incarcerated fathers often feel their children's mothers actively prevent them from having contact with their children. Maternal gatekeeping may also depend on the relationship between the children's mother and the incarcerated father's own mother. The children's mother may allow the incarcerated father's mother to facilitate contact between the children and the incarcerated father.

During periods of incarceration, family members maintain contact through letter writing, phone calls, and in-person visits. Incarcerated mothers, compared to incarcerated fathers, tend to have more contact with their children. The type and the frequency of contact between offenders and their family members often depend on individual correction facility policies, how far the facility is from where family members live, and time left to serve. For example, letter writing is more common than phone calls and in-person visits. Based on data from the late 2000s, 70% of state inmates and 84% of federal inmates send and receive letters, while 53% of state inmates and 85% of federal inmates receive phone calls, and around half (42% of state inmates and 55% of federal inmates) receive in-person visits. Women's incarceration facilities typically have less restrictive communication and visiting policies than the facilities where men are incarcerated. When family members live closer to offenders' place of incarceration, there is more in-person visitation. Finally, contact becomes more common when offenders have less time left to serve.

In-person visitation deserves particular attention because it is the context in which offenders can be physically present with their family members. However, in-person visits are subject to

various policies and rules, which make it difficult to engage in warm and supportive family interactions. For example, visiting environments are noisy and, in an effort to control offenders' movements, do not provide family's privacy. It is also common for offenders and family members to be required to remain seated and physical contact be limited to hugs at the beginning and end of visits. Additionally, some jails allow only no-contact visits. In no-contact visits, offenders and family members are physically separated and must communicate through phones. Finally, visitation can lead family members, particularly children, to relive the pain and distress they felt when offenders were originally arrested and imprisoned. Younger children in particular may not be able to understand why their parent is confined and become upset when they have to leave. Despite these challenges, many families believe that in-person visits are important experiences that help them strengthen family relationships. For example, when offenders perceive fewer problems with in-person visits, they report feeling closer to their children and feeling less parenting stress. These visits may also promote family reintegration following confinement, which decreases offender recidivism.

Incarceration and Parenting

Incarceration affects parenting by undermining offenders' parental identity and preventing them from engaging in direct caregiving. In terms of parental identity, a significant concern among incarcerated parents is feeling as though they matter in their children's lives. Being unable to parent their children while confined can lead offenders to experience distress over the loss of parental identity. It is important to note, however, that offenders' pre-incarceration parenting has not been well researched. That is, it is unclear just how engaged incarcerated parents were prior to confinement. Even if parents and children had limited contact prior to incarceration, however, that does not mean that parents and children are unaffected by incarceration. Incarcerated parents, mothers in particular, also redefine what it means to be a *good parent*. *Good parents* during incarceration may be viewed as those who are actively trying to improve their parenting skills as well as being knowledgeable about what is going on in their children's lives.

Therefore, incarcerated parents will often take advantage of parenting education and life skills training programs offered in correctional institutions. These programs allow them to prepare for reunifying with their families following release.

Due to physical separation and constraints during in-person visitation, it is difficult for incarcerated parents to engage in meaningful, direct caregiving. In general, parents maintain their relationships with their children through shared leisure and provisions of warmth and support, especially during times of distress. Incarceration prevents parents from engaging in those behaviors, leading offenders to question what role they have in their children's lives. A desire to remain an active presence in their children's lives leads many incarcerated parents to focus on being a cooperative co-parent. During incarceration, co-parenting typically involves (a) communicating with children's caregivers; (b) learning about children's activities, needs, and well-being; and (c) discussing children's care needs. Therefore, by engaging in co-parenting, incarcerated parents are able to contribute to their children's ongoing care and development. Being an active co-parent allows offenders to remain knowledgeable about what is going on in their children's lives and make suggestions regarding what type of care and opportunities they need. Co-parenting is also related to frequency of offender-child contact during incarceration as well as parents' successfully transitioning into parenting roles after release. Incarcerated parents' opportunities to co-parent, however, are determined by children's primary caregiver. If a child's caregiver does not support an offender's efforts to be a co-parent, attempts to co-parent may be blocked. As the children of incarcerated mothers are most commonly cared for by a maternal relative, these caregivers are often, but not always, supportive of mothers' efforts to be active co-parents. Incarcerated fathers, on the other hand, may have fewer opportunities to co-parent if they no longer have a relationship with their children's mothers.

Reintegration Into Families Following Incarceration

Despite the challenges in maintaining family relationships while incarcerated, most offenders plan to return to their families following release from

confinement. The process of reintegrating with their families after incarceration, however, comes with its own set of challenges. Offenders are often dependent on family members in ways that prevent them from enacting typical adult roles. For example, offenders are often dependent on their families for housing and financial support. Offenders are also unsure if they will be allowed or able to return to the family roles they held prior to incarceration. For example, during incarceration, offenders may have missed significant developmental milestones of their children. Thus, they may not feel they know their children well enough to be able to be supportive and effective caregivers. Despite the difficulties offenders and their families may experience during reintegration, if they are able to establish roles and routines, offenders may be less likely to recidivate.

Final Thoughts

Incarceration is a challenging context for maintaining family relationships. Although there are several forms of contact (e.g., letters, phone calls, and in-person visits) offenders and their family members can use during periods of incarceration, these mechanisms do not allow for the typical activities families use to strengthen their relationships. As a result, it is common for offenders and family members to become less close during incarceration. Offenders' relationships with their children are particularly impacted by incarceration. Despite the challenging context of incarceration, most offenders and their families maintain some form of contact and plan to reunify after release. If they are able to reestablish appropriate family roles during reintegration, family relationships can provide offenders with important sources of financial and social support. Such support can help them avoid recidivism.

FAMILY SYSTEMS THEORY OF CRIME

Family systems theory is a theory of human behavior introduced by Murray Bowen that suggests individuals are best understood as a part of their family unit rather than in isolation. It evolved from general systems theory and its application to the complex interactions between family members and other social systems. Families are considered systems because of their inter-related elements, coherent behaviors, regular interactions, and interdependence with one another. It is natural that family members are connected emotionally. This connectedness and related interaction make the family members function interdependently. According to family systems theory, one family member changing his or her functioning is followed by reciprocal changes in the functioning of other family members and, in turn, the whole family unit. Family systems theory allows a better understanding of family emotional and relationship processes and symptom development. It has shown to be effective in understanding human behavior, symptom development, and the family as it relates to crime. This entry discusses family systems theory as it relates to crime and criminal behavior. It introduces concepts of family system theory and discusses estimates of family-related criminal behavior, the family's role in crime and delinquency, and treatment recommendations to reduce the risk of criminal behavior in families.

Understanding the Concepts of Family System Theory

Family systems theory is a holistic model that offers an effective framework toward understanding both family emotional and relationship processes and symptom development. *Family* is defined as a blend of an emotional system and a relationship system. The family environment consists of the immediate (nuclear) family, the extended (multigenerational) family, and the interaction with the broader social system. Family systems theory accentuates how patterns of behavior in relationships are transmitted to future generations as well as the influence of this transmission on behavior.

There are eight interconnected concepts of family systems theory. These are triangles, differentiation of self, nuclear family emotional system, family projection process, multigenerational transmission process, emotional cutoff, sibling position, and societal emotional process.

Triangles

A *triangle* in this context is a three-person relationship system and is considered the most stable relationship within a system. Positive or negative outcomes can result from triangles depending on how anxiety and reactivity are managed by the members. Bowen postulated that if one member of the triangle remains calm and in emotional contact with the other two, the system automatically calms down. Triangles may contribute to the development of symptom formation.

Differentiation of Self

Differentiation of self refers to the development level of a person's sense of self. Family members may influence how individuals in the family think, feel, and behave. Individuals vary in their vulnerability to these influences. *Level of differentiation* refers to the degree that a person can think and act for him- or herself when coping with emotionally laden issues. It also refers to the degree to which a person can tell the difference between thoughts and feelings. The less developed a person's sense of self, the more others may influence the individual's functioning.

Nuclear Family Emotional System

The four basic relationship patterns in the nuclear family emotional system that cause problems in the family unit are marital conflict, dysfunction in one spouse, impairment of one or more children, and emotional distance. These relationship patterns result in anxiety developing in certain parts of the family system, which commonly results in symptomatic behaviors.

Family Projection Process

The family projection process describes the way parents transmit their emotional problems to a child. The projection process can impair the functioning of one or more children and increase their vulnerability to negative behavioral symptoms. The functioning of the child automatically improves when parents can manage their own anxiety and resolve their own relationship issues.

Multigenerational Transmission Process

The concept of the multigenerational transmission process describes how levels of differentiation between parents and their offspring, relationship patterns, and the process of managing anxiety are transmitted among the members of a multigenerational family. One of the ways family patterns are transmitted across generations is through relationship triangles.

Emotional Cutoff

The concept of emotional cutoff describes how individuals manage their unresolved emotional issues with parents, siblings, and other family members by reducing or totally cutting off emotional contact with them. Individuals look for other relationships to substitute for the cutoff relationship. These new relationships prohibit the family system from repairing itself, and family members become vulnerable to symptoms.

Sibling Position

Observing the impact of sibling position on the development and behavior of families in his research, Bowen noted the impact on the family unit. Oldest, youngest, and middle children maintain certain

functional roles in families. For example, oldest children will typically demonstrate characteristics of responsibility, organization, and behaviors that are pleasing to parents. Oldest children may maintain a functional role in the family as a surrogate parent when other siblings arrive, due to their protective and responsible nature. Middle children often become experts at negotiation and compromise. They tend to be unbiased and levelheaded, taking on the role of peacemaker and negotiator of the family. Youngest children typically receive the least discipline, fewest responsibilities, and the most attention by being funny and adorable. Their functional role in the family is limited, as they are often carefree, living their lives in their social surroundings. These roles influence how family members interact with one another as well as outside systems.

Societal Emotional Process

The concept of *societal emotional process* describes the influence of emotional behaviors on a societal level. Environmental stressors such as overpopulation, limited natural resources, poverty, unemployment, homelessness, and limited access to health care are all potential stressors that contribute to an emotional deficit in society.

Estimates of Family-Related Criminal Behavior

According to the National Survey of Children's Health, more than 5 million children have a parent in state or federal prison. The Bureau of Justice Statistics reported in a 2011–2012 national survey that more than 120,000 incarcerated mothers and 1.1 million incarcerated fathers are parents of minor children (under age 18 years). The Office of Juvenile Justice and Delinquency Prevention reports indicate a decrease in the annual rate of youth in confinement by 6.5% to 225,000 from 2005 to 2014.

Parental incarceration has devastating consequences for family stability, couple relationships, and economic resources available to caregivers and children. It creates stressful circumstances for children. The notion that children of incarcerated parents are more likely to be incarcerated than their peers and are subject to criminal activity, however, is a misperception with no basis in existing research. Parental incarceration is now recognized as an adverse childhood experience and is

distinguished from other adverse childhood experiences by the unique combination of trauma, shame, and stigma.

The Role of the Family in Crime and Delinquency

Considering the relationship between family factors and criminal behavior, the literature suggests that the family is critical in a child's possible involvement in crime. Theory and research in the area of crime and delinquency have increasingly emphasized the importance of family processes in explaining the development of deviant behavior. Criminologists are considering family-related issues (e.g., marital violence, child abuse, and influence from unmarried parents living together) in their investigations of antisocial behavior. Other children experience many of the risk factors that the children of incarcerated parents experience (e.g., parental substance abuse, mental health, inadequate education). Parental incarceration, however, increases the risk of children living in poverty or experiencing household instability, independent of these other problems. In turn, these environmental stressors cause anxiety and disruption within the family system.

Families and children of incarcerated parents experience a set of unique difficulties as a result of parental incarceration. These challenges include traumatic separation; loneliness; stigma; confused explanations from adults; strained parenting; reduced income; and home, school, and neighborhood moves. According to family systems theory, negative behavior symptom formation may occur when a family member does not successfully manage the emotional disruption in the family system. Although research suggests that parental incarceration is associated with higher risk for children's antisocial behavior, family systems theory offers the possible supposition that the children's antisocial behavior is the result of relational dysfunction.

Family factors are not the major reason most individuals participate in criminal behaviors. For example, when meta-analyses were conducted examining a range of factors and their relationship to the onset and continuation of crime, family factors were commonly not the higher correlation. The average correlation across family factors was typically similar to the correlation across all

factors. From a family systems perspective, it is unsurprising that individual family factors were never the largest correlation. The negative impact is not related to the individual family factors but rather the disruption of the family system. The difficulty experienced by family members taking on new roles in the family system due to the incarceration of a parent or spouse has a stronger negative impact than the incarceration alone.

Treatment Recommendations to Reduce the Risk of Criminal Behavior

A family systems approach is recommended as a highly effective treatment model for severe behavioral problems in both adolescents and children. Early intervention programs with a family focus include family support and education as well as family interventions designed to improve child-rearing practices. These promote a decrease in juvenile delinquency. Family-focused interventions (e.g., family behavioral treatment, training in effective parenting approaches, culturally specific family therapies, brief strategic family therapy [BSFT], and multisystemic treatment approaches) consistently show a reduction in delinquent behavior, such as rearrests, recidivism, and truancy following treatment.

Functional Family Therapy

Functional family therapy is a family behavioral intervention. This model of treatment combines systems concepts, social learning theory, behavioral ideas, and cognitive processes that attempt to understand family problems and how they function for the family. The goal of therapy is to modify interpersonal communication and family interactions as a way to increase reciprocity and positive reinforcement in interpersonal interactions. Families of delinquent youth are moved from negative to more normal interactional patterns and interpersonal communication. In general, functional family therapy therapists are trained to modify family behavior through modeling, prompting, and reinforcing appropriate behavior.

Parent Management Training (PMT)

PMT is an extensively researched parenting approach to the treatment of delinquent youth and their families. PMT is based on the idea that

parents can be trained to be change agents for their children's problem. Therapy focuses on teaching parents to respond more effectively and consistently, attend to specific behaviors, praise more, and criticize less. From a family systems perspective, this change in interactional patterns within the family is meant to shift the dysfunctional family patterns so that children's prosocial behaviors are reinforced and negative problem behaviors are ignored or punished. A possible drawback in the use of PMT is the need for active participation by the parents when the parents may not be willing or able to participate.

Multisystemic Treatment (MST)

MST is an alternative treatment approach that is a significant departure from more traditional strategies. This family-based therapeutic approach has been viewed as a highly promising treatment for complex psychosocial problems in children and adolescents. The goal of MST is to provide an integrative, cost-effective, family-based treatment that results in positive outcomes for adolescents who demonstrate serious antisocial behavior. MST focuses on the individual youth and his or her family, peer context, school or vocational performance, and neighborhood or community support. MST has demonstrated decreased criminal activity and incarceration in studies with violent and chronic juvenile offenders.

BSFT

BSFT is a structured, time-limited, family-based approach that combines both structural and strategic interventions. The goal of BSFT is to improve youth behavior by improving family relationships that may be directly related to the youth's behavior problems and to improve relationships between family members and other important systems that may be influencing the youth. Consistent with family systems theory, BSFT is based on the assumption that the family is one of the most important socializing systems in the lives of youth and provides the foundation for child development. BSFT conceptualizes and intervenes to change youth behavior problems at the family level.

From a family systems perspective, family-focused interventions and family strengthening programs are essential in the prevention of

delinquency and juvenile crime. Family involvement is essential in the rehabilitation of incarcerated juvenile offenders and the reduction of the intergenerational transmission of criminal behaviors. From a systemic perspective, recidivism rates will be high as long as family interventions are not provided to delinquent youths and their families of origin during incarceration as well as upon their return into the family system. Interventions based on family systems theory have proven successful in the adjustment of the family during incarceration and assistance toward reintegration of the returning family member.

FAMILY-FOCUSED THERAPY

Family-focused therapy for juvenile and adult offenders includes evidence-based treatment models that target the family risk and protective factors associated with delinquency, antisocial behaviors, and substance-related crimes. It also

involves psychoeducational programs designed to enhance the quality of parent–child and marital relationships and thus promotes family resilience and protects individuals against a criminal lifestyle. This entry describes the targets and goals of family-based interventions and provides a summary of the research on family-focused therapy and recidivism. It also highlights gaps in services for specific populations.

Familial Risk and Protective Factors

Family-focused therapy for juvenile and adult offenders is based on empirical knowledge about family dynamics that influence individuals' criminal trajectories, particularly during childhood and adolescence. The familial factors that increase children's risk for delinquency are poor parent–child relationships; harsh, permissive, or inconsistent discipline; lack of parental supervision; family violence, including child abuse and neglect; family conflict; low levels of positive parental involvement; and parental antisocial history. By contrast, warm and positive parent–child relationships and parental monitoring help to prevent the development of conduct problems.

Research on family dynamics and recidivism has also found a link between romantic relationships and desistance from crime in adulthood. Having a spouse or intimate partner may represent a source of instrumental support and accountability for adult offenders who aim for a prosocial lifestyle in the community. Romantic partners exercise a positive influence through processes of supervision and monitoring. They also provide assistance with housing, transportation, or food as well as emotional support that protects individuals against stressful life events. However, relational conflict and partners' involvement with drug use or distribution moderate the positive effect of romantic relationships on adult antisocial behaviors. In addition, research suggests that for female offenders, intimate relationships are more likely to serve as a pathway to crime than for men.

Family-focused therapy for juvenile and adult offenders aims to activate the familial processes that protect individuals against the intrapersonal, relational, and environmental factors associated with recidivism. The family is the focus of intervention; delinquency and violence reduction are

the desired outcomes of a multisystemic approach to the treatment of antisocial behaviors.

Family-Focused Therapy for Juvenile Delinquency and Criminal Conduct

Family-focused therapy for juvenile delinquency includes evidence-based treatments that have been disseminated and evaluated in diverse community settings nationally and internationally. Multisystemic Therapy (MST), Functional Family Therapy (FFT), and Treatment Foster Care Oregon (TFC; formerly called *Multidimensional Treatment Foster Care*) have been designated as model violence clinical programs by the Office of the U.S. Surgeon General and the Center for the Study and Prevention of Violence at the University of Colorado. Family-based programming for adult offenders is at an early stage of development. For the most part, it involves family case management, support services, and parent training delivered in the community and behind bars.

Effectiveness of Family-Focused Therapy

MST is a community- and family-focused approach to the treatment of youth's chronic and severe antisocial behaviors, which integrates the principles of social learning and social ecological theory as well as structural and strategic family therapy. The model has also been adapted to target the needs of specific populations, such as juvenile sex offenders and substance-using youth. Clinical services are brief and intensive and are delivered at home, at school, and in the neighborhood where the violent or problematic behaviors occur. MST–Family Integrated Transitions is an adaptation of the model for adolescents in juvenile detention facilities. Treatment begins during detention with the teaching of dialectical behavior therapy skills to youth and caregivers separately and is followed by intensive MST services in the community. MST is one of the most researched family-focused treatment programs with over 20 randomized controlled trials in university- and community-based settings. These studies have produced evidence that MST reduced youth recidivism and out-of-home placement rates, supported sobriety, and improved family and peer relationships.

FFT is a manualized, family-based, clinical program for at-risk youth and families with behavior, substance use, and relational problems. In FFT, the family is the primary focus of intervention, and juvenile delinquency is understood in the context of relational dynamics. Service delivery occurs in three phases with specific goals and interventions. The targets of therapy are engaging families in treatment, increasing clients' motivation to change, building protective skills (e.g., parental monitoring), and relapse prevention. FFT has a well-established record of effectiveness based on 40 years of research in university- and community-based clinics. Studies have shown that youth who received FFT services were less likely to recidivate and be placed in out-of-home settings. However, for both MST and FFT, therapy outcomes varied with treatment adherence. Positive effects were found only for those clinicians who delivered the programs as specified by the clinical protocols. Like MST, FFT is one of the most widely disseminated family therapy models in the United States and abroad. FFT is also the first and only model of family therapy to be adapted and tested with adult probationers. Scientific findings indicate that FFT for adult offenders helps reduce family conflict, improve individual functioning, and increase family cohesion. It may also contribute to reducing the risk of recidivism. These results suggest that FFT is a promising family-focused approach to adult offender rehabilitation and reentry.

TFC is a multidimensional family-focused program that offers an alternative to residential treatment and incarceration for adolescents with severe and chronic antisocial behaviors. Youth receive mentoring and individual therapy while living under the close supervision of foster families. Foster families are trained to implement youths' behavior management plan, encourage prosocial behaviors, and emphasize teens' strengths. Primary caregivers participate in parent management training followed by family therapy with their adolescents. The goal of conjoint therapy is to prepare the family for reunification and to create an environment that will support continued behavior change. Research findings indicate that, compared to their peers in residential treatment facilities, youth who participated in TFC had lower rates of recidivism and incarceration at

follow-up. In addition, TFC has been shown to reduce teen pregnancy and to decrease the length of incarceration and number of criminal referrals among chronic adolescent female offenders.

Brief Strategic Family Therapy is a promising family-focused model for the treatment of juvenile delinquency. Originally designed to target adolescent substance abuse in Cuban immigrant families, Brief Strategic Family Therapy is a short-term, systemic, and problem-focused approach that focuses on the repetitive patterns of family interactions that maintain youth drug use and drug-related behaviors. A number of clinical trials have evaluated the outcomes of Brief Strategic Family Therapy and established that the program was efficacious in reducing conduct problems and association with antisocial peers among African American and Hispanic adolescents.

Likewise, Multidimensional Family Therapy is an evidence-based, comprehensive, family therapy program for juvenile substance abuse and substance-related behavior problems. The results of randomized controlled trials showed that Multidimensional Family Therapy was superior to other treatment approaches as relates to teens' drug abstinence and rates of arrest. Multidimensional Family Therapy for juvenile reentry is an adaptation of the model for youth in detention facilities. It engages the family in prerelease planning while the adolescent is still in custody and accompanies the youth and their family members in the community where clinical work focuses on reintegration, family relationships, and parenting.

Effectiveness of Parent Training and Marriage Education Programs

Parent Management Training—Oregon Model is a family intervention program that focuses on the development of effective parenting strategies to prevent and reduce delinquent behaviors in children and adolescents aged 3–16 years. Caregivers learn skills that promote competency and resilience and protect children from environmental risk factors such as poverty, mass trauma, and dangerous neighborhoods. These skills include limit setting, positive reinforcement, monitoring, and problem-solving. Parent Management Training—Oregon Model was found to reduce deviant peer association and to lower rates of juvenile arrest.

Delivered by trained prison chaplains in Oklahoma's correctional facilities, the Prevention and Relationship Enhancement Program (Inside and Out) is a marriage education program for incarcerated individuals and their intimate partners. Prevention and Relationship Enhancement Program Inside and Out aims to strengthen intimate relationships through psychoeducation and skill training, with a focus on problem-solving, communication, affect management, safety, and positivity. There is limited evidence supporting the success of the program and its effects on criminal conduct post-release; however, the couples who participated in Prevention and Relationship Enhancement Program Inside and Out reported reduced level of conflict and increased relationship satisfaction, connectedness, and commitment.

Service Gaps and Population-Specific Needs

Familial processes, such as parent-child conflict, low parental warmth, and harsh and inconsistent parenting play a major role in teen delinquency and involvement with juvenile justice systems. Girls, in particular, are more likely to experience elevated risk in the family domain than boys. Familial problems, together with exposure to violence and substance use, are stronger predictors of girls' recidivism compared to boys. In addition, harsh punishment and low parental warmth are associated with the development of girls' externalizing behavior problems at ages 7 and 8 years and are significant predictors of girls' delinquency in mid-adolescence.

There has been extensive research demonstrating the effectiveness of family-focused therapy for juvenile delinquency. However, most evidence-based, family-focused interventions for youth violence were developed at a time when boys represented the majority of the juvenile justice population and when knowledge about the correlates of girls' delinquency was limited. With the exception of TFC, few family-focused clinical interventions have been evaluated for their gender-specific impact on justice-involved girls, and research has yet to investigate how girls experience family-based programming originally designed for at-risk boys.

Similarly, there is a need for research that identifies the familial processes associated with desistance from crime in adulthood as well as a need for cohesive, family-focused services that support adult offender rehabilitation and reentry. Family involvement in correctional programming is a key process in the development of strong social support networks and the successful rehabilitation of adult offenders in their communities. Most family-focused interventions for adult offenders are case management and psychoeducational services delivered in the community that do not require the direct participation of family members. Evidence-based family therapy for juvenile delinquency, such as FFT, can serve as templates for the development of comprehensive, family-focused programs for adult correctional populations that aim to activate family processes linked to resilience and positive rehabilitation and reentry outcomes.

FAMILY-ORIENTED CORRECTIONAL PROGRAMS

Family-oriented correctional programs are services and activities organized to help men and women in prison maintain family ties and prisoners' relatives and significant others manage stresses and concerns related to incarceration. Men and women in prison had family roles and responsibilities prior to their incarceration. Many provided the major sources of income for their families; others managed households and carried out obligations and commitments important in sustaining family life. Many mothers, as well as fathers, resided in single-parent homes and, at the time of their arrest, had primary responsibility for the care of their children. The majority of prisoners are parents of minor children.

Criminal justice system involvement takes its toll on individuals and families and has a negative effect on family relationships. Families and children are teased, shamed, and sometimes discriminated against, as if being related to a person in prison is a crime in and of itself. Children sometimes feel that they are the cause of their parents' problems. They often worry about their own circumstances

and sometimes behave in inappropriate ways. Families lose the income of prisoners who had been contributing financially and incur new expenses for attorney services, legal fees, prisoners' personal items, prison visits, and telephone calls. The maintenance of family relationships is challenged by uncertainties about the crime that was committed and prison conditions, questions about individual faithfulness, prison policies that limit communication, and the absence of private family moments. The pain and hurt of separation are ongoing and confusing and a lot to bear for children and adults alike. Family programs offered by correctional institutions and community organizations provide opportunities for prisoners and their families to deal with these family matters. This entry discusses the different types of family-oriented correctional programs, their goals, and their outcomes.

Program Types

The most universal family-oriented correctional program is prison visiting. Most prisons and jails allow visitors to come to the facility at designated times to see an incarcerated individual. Traditional visits range from 15 min in jails to 6 hr or more in prisons. Visitors typically must be on a prescreened list, adhere to a dress code that may or may not be posted, submit to a search, and present a state-issued identification. Noncontact visits that take place via telephone with plexiglass separating visitors and incarcerated persons are common in jails. Visiting rooms staffed by correctional officers where persons sit at tables or in rows of chairs are more common in prisons. These contact visits allow prisoners and their visitors to hold hands or embrace, though often only at the beginning or end of visits.

Video visits allow family members and prisoners to visit remotely by computer. Family members sitting at a computer screen in a community location are able to see and talk with an incarcerated person sitting at a computer kiosk in a correctional facility. Video visits supplement regular visits in prisons; in jails they, more often than not, replace in-person visits. Some correction departments charge a fee for video visits, similar to the fees individuals pay to talk with a prisoner on the telephone. Others charge visitors a fee to be processed and approved for a prisoner's visiting list.

Extended family visits, also referred to as *family reunion* or *conjugal visiting programs*, are not standard programs in U.S. correctional facilities. Only four states offered these programs in 2016, a decrease from 13 in the early 2000s. These extended visiting programs allow prisoners to spend private time overnight with their legally married spouses and other family members in a trailer or apartment on prison grounds. Program participants must meet criteria established by corrections officials and go through a screening and approval process. States that discontinued programs usually did so following news media coverage regarding a prisoner's spouse becoming pregnant or a rule violation during a visit. The cost of running the program is often cited as the official reason for termination.

Visiting centers run by community organizations and located near prisons provide complementary services for prison visitors. The centers provide a place where visitors who have traveled a long distance can rest and freshen up prior to the visit, get refreshments, or obtain clothing that fits a prison's dress code. The centers also provide information on lodging or have accommodations where guests may spend the night or wait for public transportation.

Almost all prisons for women and the majority of those for men indicate that they offer parenting programs. Most often, this is a parent education class. The curriculum for different programs suggests that there is an underlying assumption that prisoners can become better parents if they learn basic child development and disciplinary approaches. Some courses also cover ways that parents can be positively involved in their children's lives during incarceration and following release. Others help parents become more attuned to how children may be affected by their parents' absence. Parent education classes are sometimes used as a prerequisite for participation in other parenting programs.

Extended parent-child visits or special visiting rooms for parents and children are offered as a component of parenting programs at a few correctional facilities. Special visits at facilities for women include overnight or weekend visits where mothers can interact with their children in a home-like setting. Boys 12 years of age and older, however, are typically excluded. They eat, sleep,

and prepare meals together and participate in staff-directed sports and social activities with other mothers and children. Daylong special visits allow mothers and children to spend time together, without the child's other parent or caregiver present, often in a setting other than the regular visiting room. Activities include games, arts and crafts, or a structured program, such as a Girl Scout troop meeting.

Prison nurseries allow mothers who deliver while in prison to keep their babies with them for a year or more in designated prison units. Residential programs allow mothers who are nonviolent offenders and meet other criteria (e.g., no rule violations) to keep their preschool children with them either at the prison or in a secure community setting. Although prison nurseries have been in existence since the early 1900s, they have not been adopted by most correctional systems. Critics of nurseries and residential programs in prison indicate that the children, like the mothers, are incarcerated and subject to myriad prison rules and regulations. Proponents of the programs cite the importance of mother-child bonding and point to the best practices of established programs like the nursery at Bedford Hills Correctional Facility in New York.

Opportunities for fathers to visit alone or one-on-one with their children are practically nonexistent. Special visiting rooms where parents may engage in meaningful activities with their children are rare in men's prisons. Areas that are identified as special for children are seldom more than visiting room areas with a few used books, cards, and games. An exception is the children's visiting room at Sing Sing Correctional Facility in New York. The room is organized much like rooms in day-care centers and after school programs and staffed by prisoner volunteers trained by a community organization.

Community-based programs for children whose parents are incarcerated focus on helping children engage in activities that promote their growth and development and deal with their feelings about their parents' incarceration. Mentoring programs provide children with individual attention and adult role models during their parents' absence. Mentors take children on social outings and encourage them to do well in school and at home. Mentoring programs run the gamut from highly

structured programs operated by traditional social services agencies with external funding to informal services provided by small, faith-based groups.

Children's support groups provide outlets where prisoners' children can meet with other children who are also experiencing parental incarceration. Support groups typically include social and recreational activities as well as opportunities for children to talk about their experiences and feelings. Participants sometimes receive holiday and birthday gifts or prizes at different events. Although monthly meetings are the norm, overnight group events and summer camps are also common. Social service agencies and church groups that provide transportation services taking children to visit their mothers in prisons often use the long rides to the prison as a support service. Adults who staff the buses and vans use the travel time to the prison to prepare children for the visit and the ride home to debrief them. Children are able to ask questions, share their thoughts with other children, and express their feelings about the visit in a safe and nonthreatening environment.

Support groups and services for adult family members (e.g., wives, girlfriends, and children's other caregivers) are often short lived and operate without program grants or contracts. Most are multipurpose groups that provide emotional support, information resources, and assistance with prison issues and life challenges. Many are started by prisoners' family members to advocate for change around prison policies, such as high telephone rates and visiting rules and practices. Few are run by established social service organizations. The exceptions are the marriage education and counseling programs offered as part of the federal government's responsible fatherhood and marriage strengthening initiative. Since 2007, these programs have been offered in different prisons for couples in committed relationships who have a child together. Co-parenting, conflict management, and marital topics are discussed in male-only and couple groups led by community professionals.

Program Goals and Outcomes

Corrections departments usually affirm the importance of family relationships and the maintenance of family ties as a reason for prison visiting and

other family programs. Articles about family-oriented correction programs and funding proposals often identify other goals as well. These goals include prevention of recidivism, prevention of intergenerational crime, improvement in prisoners' behavior, and reduction of prison rule violations. Few family-oriented programs have undergone rigorous testing and evaluation, but there is logic underlying these goals.

The maintenance of family ties is connected with post-release success. Men in prison who have visitors have lower recidivism rates than those who do not. Participants in extended family visiting programs have lower recidivism rates than nonparticipants, though it is unclear if the program itself is the reason. Pre- and posttests indicate that participants learn the material in parent education courses and gain new understandings about themselves and their partners in marriage education and couple counseling. Children in mentoring programs show improved school performance and fewer behavior problems, though findings sometimes reverse when program participation ends. Participants in extended family programs have lower rule violations than others, as rule violations would lead to their dismissal from the program.

Program evaluations do not indicate, however, if parent education courses improve parent-child relationships or if parent participation leads to different parenting practices. Nor do they indicate if children involved in mentoring programs are less likely than their peers to become involved in criminal activity as adults. Similarly, there is limited information on the effect of participation in parenting programs on reunification of households and children's well-being following parents' release. In many cases, the most pronounced finding is that prisoners and their relatives and significant others appreciate the opportunity to be involved in activities with a family focus. A statement voiced often in formal evaluations and program reports is that someone cared enough to offer programs and services that acknowledge prisoners' family roles and their families' concerns and needs.

FEAR OF CRIME

Fear of crime is an important strand of criminal psychology that has garnered much attention since the mid-20th century. However, fear of crime has yet to have a universally accepted definition, and as the focus of policing turns increasingly to cyber-crime, the concept potentially needs revisiting once again. According to Chris Hale, at its most basic level, the fear of crime refers to the fear of being a victim of crime rather than the fear of crime itself (or the probability of being a victim of a crime). Several definitions have been put forward: John E. Conklin defines it in terms of a sense of personal security in the community, whereas Jeanette Covington and Ralph B. Taylor defines it more in terms of the emotional response to a violent crime and physical harm. Other definitions have suggested that the fear of crime is an emotional response of dread or anxiety to crime or symbols that a person associates with crime.

Research suggests that high levels of fear affect society and individuals in a variety of ways. On an individual level, those who report high levels of fear of crime are more likely to report poor health and a lower quality of life, while communities that are disproportionately more likely to feel unsafe when out after dark also express lower levels of trust and are less likely to think their neighbors are friendly. The causal relationship between these perceptions is not clear, but measures of fear of crime are typically indicators of some level of social harm.

How Is Fear of Crime Measured?

The measurement of fear of crime is as contested as the concept itself. Historically, the measurement has relied on survey data, but a number of studies have sought to validate this and develop new ways of understanding public perceptions.

Perception of safety questions—such as “How safe do you feel walking alone in this area after dark?”—has received criticism and has been shown to display *mismatches*, whereby it was clear that quantitative and qualitative research methodologies do not produce the same findings. Other measures have become standard and validated, such as asking participants to summarize their levels of worry about specific crimes and the likelihood of becoming a victim.

However, long-standing fear of crime measures have begun to take a back seat to measures—and accompanying initiatives—focused more on public confidence in law agencies. For instance, in the United Kingdom, in response to 10 years of statistics demonstrating significant decreases in crime rates but without any accompanying shifts in public perceptions of levels of crime, a single measure of police performance was introduced in 2009 to evaluate the impact of crime policy, based on a survey measure of public confidence in policing. Public perceptions were prioritized ahead of recorded crime and detection rates, the rationale being that if the rate of crime falls, but people do not have the confidence that this is happening in their neighborhood, then their quality of life will continue to be affected and the benefits of reduced crime would not be realized. This matters because it undermines the police and government efforts to engage the community through crime reporting,

intelligence gathering, and community engagement activities. This single measure was subsequently replaced in the United Kingdom by greater devolution of powers and introduction of police and crime commissioners to represent and foster public confidence in policing.

While confidence measures have taken center stage, the longer standing fear of crime measures continue to be asked in the Crime Survey of England and Wales (CSEW; formerly the British Crime Survey). In 2013/14, CSEW found that 19% of adults thought that it was either *very* or *fairly likely* that they would be a victim of crime within the next 12 months. One in seven adults (12%) were classified as having a high level of fear about violent crime, 11% about burglary, and 7% about car crime.

All of these measures were at a similar level to the 2012/13 survey, and the general trend has been flat for a number of years. This is in contrast to actual crime levels, which have, broadly, declined in the United Kingdom for a number of years, although this is not universal across crime categories. The latest release of the CSEW has shown a 7% decrease in incidents but increases in some of the lower volume but more serious types of police-recorded violence.

Despite this complexity, it still seems clear that there is a long-term gap between trends in the likelihood of being a victim of crime and the perceived likelihood of being a victim of crime or broader measures of fear of crime. This phenomenon is not unique to the United Kingdom, and the United States has seen a sharp decline in violent crime rate since the mid-1990s, but a 2011 Gallup Poll found that the majority of Americans continue to believe that the nation's crime problem is getting worse. Across Europe, this phenomenon has also been observed; fear of crime has increased slowly but steadily across the European Union as a whole between 1996 and 2002 (with the only member state where there has been a continuous decline since 1996 in the feeling of insecurity is Germany), while crime trends decreased.

Why Do These Perception Gaps Exist?

It seems highly likely that the media have a significant influence on the public's views. The CSEW 2013/14 found that among adults the most cited

source of knowledge about levels of crime in the country was news programs on television or radio (67%). Other common sources mentioned were word of mouth or information from other people (32%) and newspapers (*tabloid*, 31%; *local*, 31%). Sources of information are important in determining how the influence will sway public opinion for instance; one study by Paul Williams and Julie Dickinson found that 65% of newspaper crime reporting involved violent crime, despite these types of crime making up only 6% of recorded crime. Chris Greer found that all media tend to exaggerate the extent of violent crime while also suggesting that different types of crime and victims derive different newsworthiness, leading in some cases to long-term collective moral outrage and media campaigns instilling in the public psyche the prevalence of serious violent crime.

This relates to another reason suggested for the perception gap; there are a number of high-profile or *signal* crimes that have a greater impact on perceptions than other crimes, and these signal crimes—in contrast to some other crimes—are not decreasing in the numbers reported. There is some evidence for this. For example, according to the Home Office, the number of homicides in England and Wales rose from 71 to 574 between September 2014 and September 2015—an increase of 14%, fueled by rises in knife and gun crime.

What Drives Public Perceptions of Crime?

Looking across a number of studies, there are several common factors associated with fear of crime at individual and societal levels. First, there are significant demographic variations in perceptions of the fear of crime. Gender is one of the most consistent predictors of differences in the reported level of fear of crime. In nearly 50 years of research in the fear of crime, the distribution in the population, and its determinants, virtually all studies that integrated sex as an independent variable have found significantly higher levels of fear that are reported by women than by men.

In 2015, the UK Office for National Statistics also found that women were more likely than men to have believed that crime had risen in recent years. This was true for crime across the United Kingdom both as a whole (68% and 55%,

respectively) and locally (36% and 28%, respectively). A broader conceptualization of worry might partially explain why women had a higher level of worry about being a victim of violent crime compared with men (18% compared with 6%). The pattern was similar for fear of being burgled with 14% of women having a high level of worry compared with only 8% of men.

There is also a relationship between age and fear of crime. Evidence suggests that those aged between 45 and 64 years were generally more worried about crime than other age-groups, aside from the exception of fear about violent crime, where those in the youngest age-group (16–24) had the highest level of worry (see Figure 1).

With regard to the national picture in the United Kingdom, the general pattern was for perceptions of crime rising in line with age, as shown in Figure 2; those aged 75 and over were most likely to view it as having risen in recent years (72%). Perceptions of crime rising locally peaked in the 35–44 and 45–54 age-groups (36% and 37%, respectively) and then reduced with increasing age. Those aged 75 and over were the most likely to think crime was rising across the country as a whole, and they were the least likely to view local crime as having risen (25%).

Therefore, variation between groups may reflect differences in perceived vulnerability rather than the perceived risk of falling victim, as it has been claimed that responses about worry are driven by feelings of vulnerability and factors associated with it. For instance, Pamela Wilcox Rountree and Kenneth C. Land have suggested that responses may encompass more than just worry about the crime being committed but also include concerns about the ramifications of different crime types and the perceived victimization that may occur. In addition, Helmut Hirtenlehner and Stephen Farrall argued that women have a higher fear of certain crime types compared with men due to their elevated fear and risk of sexual assault.

Another possible explanation for the mismatch between actual trends and perceptions is that the definition of *crime* in the public's mind incorporates far wider issues than official definitions of crime, with personal conceptions of crime potentially encompassing such things as terrorism and antisocial behavior (ASB). There is qualitative and survey evidence that suggests that this is the case, and so to the extent that these have become greater concerns since the late 1990s (which is certainly the case for terrorism and possibly the case for ASB, depending on the measure used),

Figure 1 Percentage of individuals with high levels of worry about crime by crime type and age, 2013/14 CSEW

Source: Crime Survey for England and Wales—Office for National Statistics with public-sector information licensed under the Open Government License v3.0.

Figure 2 Percentage of adults saying local and national crime levels have increased over the past few years by age, 2013/14 CSEW

Source: Crime Survey for England and Wales—Office for National Statistics with public-sector information licensed under the Open Government License v3.0.

then crime will also be seen to have increased. Perceptions of ASB and terrorism also seem to drive confidence in the government's handling of crime. ASB is a particularly important driver, with studies showing that disorder in a respondent's local area directly increases his or her view that overall local crime is rising. With terrorism, the evidence is less clear-cut, but it is thought of as an important crime issue by some, and concern about terrorism has increased substantially since the late 1990s.

Perhaps a more significant factor that is yet to be factored into relevant measures or the understanding of fear of crime is the ever-increasing influence of cybercrime. The Internet provides not only new means of committing established crimes but also opportunities to undertake new types of crime, and there have been concerns that data collection, public understanding, and enforcement definitions have failed to keep up with the changing nature of crime. The extent of this issue in the United Kingdom, for example, was highlighted in CSEW for year ending June 2015, the first to include cybercrime as a crime type, whereby a 107% increase in crime was recorded, with 5.1 million estimated cybercrimes and frauds plus 2.5 million offenses under the Computer Misuse Act—hacking, identity theft,

and malware. Revisiting the conceptual understanding of the public's fear of crime to reflect the shifting nature of crime patterns and the associated shifts in people's experiences of crime and their interactions with law enforcement agencies will be essential to ensure that fear of crime measures retain relevance.

FEDERAL BUREAU OF INVESTIGATION

The Federal Bureau of Investigation (FBI) is a federal law enforcement and intelligence agency as well as a national security organization. The FBI’s motto is *Fidelity, Integrity, Bravery*. Its headquarters is in Washington, DC, in the J. Edgar Hoover FBI Building. The FBI Academy, which hosts a 5-month required preservice training for new special agents, is located on 547 acres on a Marine Corps base in Quantico, VA, about 40 miles south of headquarters.

The FBI employs approximately 35,000 special agents, analysts, and support staff, and reports to both the attorney general and the director of national intelligence. Components of its formal mission include protecting and defending the United States against threats involving terrorism and foreign intelligence, providing leadership and training to other criminal justice organizations, and enforcing the country’s criminal laws.

Through partnerships with nations around the world, other federal agencies, and local intelligence and law enforcement organizations, the FBI uses continually advancing investigative techniques to gather and analyze information in order to prevent or halt criminal activity and ensure that such crimes are successfully prosecuted. The types of crimes investigated include cybercrime,

terrorism, public corruption, civil rights violations, organized crime, white-collar crime, violent crime, and espionage/foreign counterintelligence. This entry discusses the scope and purpose of the FBI; details many of its specialized investigative units; and summarizes its history, including changes since the terrorist attacks on September 11, 2001.

Law Enforcement Investigations

Among its core values, the FBI identifies “Fairness: Enforcing the law without fear or favor.” To that end, it prioritizes combating public corruption; protecting civil rights; shutting down organized crime; combating violent crime; investigating and prosecuting major white-collar crime; and supporting federal, state, local, and international partners in the pursuit of these goals. The bureau provides law enforcement executive training to agency partners worldwide. The National Academy course trains executive-level (lieutenant and up) law enforcement personnel and investigators from agencies around the world.

The FBI consists of 56 field offices, 381 resident agencies, and 78 international legal attaches and suboffices. The bureau reported that in 2012, it achieved 15,274 convictions, seized \$1.125 billion worth of criminal assets and drugs, and ordered the forfeiture of \$8.205 billion worth of criminal assets.

The bureau maintains the Ten Most Wanted Fugitives list, created to help increase the ability of law enforcement to locate and apprehend dangerous fugitives from justice. The Ten Most Wanted was likely conceptualized as a result of a 1949 conversation between J. Edgar Hoover, the then director of the FBI, and William Kinsey Hutchinson, editor in chief of the International News Service (predecessor of United Press International). The discussion centered on ways to join services of law enforcement and mass media to promote capture of some of the most serious criminals. A summary of the conversation was published, and public interest eventually prompted the *America’s Most Wanted* television program, which aired for 24 years before its cancelation in 2011.

Intelligence Gathering

The FBI’s Intelligence Branch was established in 2014, representing an evolution of the historical

responsibility of the FBI to fulfill responsibilities of national security and law enforcement. The Intelligence Branch includes the Directorate of Intelligence, which provides strategic support and direction to the bureau’s intelligence program. The Office of Partner Engagement manages and supports ongoing partnerships between the bureau and partnering law enforcement, intelligence, and public- and private-sector agencies to enhance intelligence and information sharing. As the FBI’s primary liaison to the domestic and international law enforcement community at large, the Office of Partner Engagement continually seeks out new partnerships and outreach programs to more effectively collaborate on gathering information potentially vital to national security. Key federal agencies included in these partnerships are the Department of Homeland Security, the Department of Justice-Office of Community-Oriented Policing Services, and the Department of Justice-Office of Justice Programs.

The FBI maintains an electronic forum, FBI Tips and Public Leads, to allow the public to provide information on suspected criminal activity or terrorism. The bureau also supports a telephone access line for community members to call and provide information on any concerns or suspicions. In addition, the Internet Crime Complaint Center, a dedicated website for reporting Internet crimes, is maintained to gather information from private citizens.

FBI Crime Lab

Since November 24, 1932, the FBI has maintained a full-service laboratory that provides forensic analysis support services to both the FBI and its partnering agencies, with the goal of solving cases and preventing terrorist acts. It is located at Marine Corps Base Quantico, in rural Virginia, and is staffed by about 500 special agents and scientists. Originally known as the *Technical Laboratory*, it formerly hosted public tours of the work area until 1974, when the FBI moved to the J. Edgar Hoover Building and the Laboratory became a separate division. Over the years, the scope of the Laboratory has expanded to support the Forensic Science Research and Training Center, which operates from the FBI Academy in Quantico.

Biometric Analysis

The FBI uses sophisticated biometrics (measurement and statistical analysis of human behavioral or physical characteristics) to help identify criminals and solve crimes. Biometrics may include palm print, iris, and facial recognition.

Since 1924, the bureau has managed the national fingerprint collection, which assists in confirming identity and solving crimes. For example, if a fingerprint is lifted from a crime scene, it can be scanned into a database to search for a match. In September 2014, the Next Generation Identification system was put into place, providing the criminal justice community with a vast and efficient electronic repository of biometric information. Among other initiatives and services, the Next Generation Identification system supports the Rap Back program, which provides ongoing monitoring of individuals who hold positions of trust (such as childcare workers and teachers). In the past, criminal background checks on these individuals provided a to-date summary of prior criminal activity. The Rap Back service provides notice to authorities regarding any future crimes committed.

The Crime Lab also supports the Combined DNA Index System that supports criminal justice DNA databases and their managing software. This technology assists DNA databases, which use the Combined DNA Index System by processing DNA collected from a crime scene (such as a sexual assault) to help identify the suspected perpetrator.

Forensic Response

The FBI Laboratory also supports the Operational Projects Unit, which provides forensic investigation of crimes. The unit uses laboratory data and resources to document crime scenes, which may include such services as conducting crime scene surveys, providing demonstrative testimony at court hearings, building three-dimensional physical models, and providing high-tech crime scene photography. These resources are invaluable not only in investigation and analysis but also as tools to obtain court convictions for criminals.

Another forensic response unit that extensively utilizes the Crime Lab is the Evidence Response Team Unit that supports field office units with training, equipment, and forensic expertise. The

Evidence Response Team Unit provides training to local field offices to ensure that standards for collecting and analyzing evidence are above reproach in technology and procedure, to ensure that the evidence can be successfully introduced in courts of law in the United States and around the world. The Evidence Response Team Unit also supports the Underwater Evidence Program that uses sophisticated equipment to conduct underwater searches to recover evidence. In addition, the Forensic Canine Program provides canine assets that facilitate human scent identification, human blood detection, and victim recovery.

History and Inception

The FBI was founded in 1908, during a time that the population was migrating west, cities were growing, and crime rates were increasing at a rapid pace. In addition, professional and political corruption was increasing. Technological advancements (e.g., automobiles) now affordable to the common man, as well as more sophisticated communication networks, also allowed criminal behavior to flourish. Theodore Roosevelt was president, having succeeded William McKinley following the latter's assassination. Roosevelt, as a proponent of the Progressive Movement, believed that the nation needed the assistance of government to ensure justice in an increasingly industrial society. Under his leadership, Attorney General Charles J. Bonaparte authorized use of sanctioned special agents to investigate selected cases of the Department of Justice. Bonaparte ordered the Department of Justice attorneys to turn over investigative matters to a team of special agents that Bonaparte had recruited. This order, occurring on July 26, 1908, is considered to be the official start of the FBI.

The initial years of the bureau were marked by undisciplined agents, limited training, political influences, and inconsistent management. However, agents were gaining experience in a broad array of investigative arenas and national security challenges, perhaps most notably in the areas of civil rights violations, human trafficking, and white-collar fraud, areas of investigation and enforcement that continue to be emphasized today. The bureau gradually gained the trust of Congress and subsequently took the lead on more high-profile investigations, such as the Mann Act (perhaps

more familiarly known as the *White Slave Traffic Act*), which was an early attempt to halt prostitution and human trafficking. By 1915, the bureau had grown from its original 34 agents to approximately 360 special agents and support staff.

When J. Edgar Hoover took the role of director of the FBI (then called the *Bureau of Investigation*), he encouraged the use of scientific analysis in the investigation of criminal matters and expected special agents to undertake training in criminological research. Hoover, who remained in the director position until his death in 1972 at age 77, is credited with building the FBI into a larger and more powerful crime-fighting agency, in part by encouraging the use of forensic laboratory services and a centralized fingerprint repository.

Changes Since September 11, 2001

After September 11, 2001, the FBI underwent a dramatic restructuring, becoming a more effective national security organization. There is a more pronounced emphasis on intelligence-driven investigations in order to more effectively detect and stop terrorist activity. The shift has included expanding intelligence capabilities, modernizing technologies, and creating improved communication with law enforcement and intelligence agency partners. An emphasis is placed on prevention of terrorist activities, while at the same time balancing the protection of citizen privacy and civil liberties. Resources have been realigned to place additional assets in counterterrorism units. Traditional partnerships have been expanded to include collaboration with overseas criminal justice agencies as well as organizations within the federal government. New relationships have been forced within industry, academia, and the public at large. In addition, the bureau created the National Joint Terrorism Task Force, which includes about 41 agencies in its membership. This priority on counterterrorism is also supported by the establishment of Field Intelligence Groups within all 56 FBI field offices as well as incorporating intelligence groups within each Headquarters operational division.

FEDERAL BUREAU OF PRISONS

The Federal Bureau of Prisons (BOP), a constituent part of the U.S. Department of Justice, is the largest prison system in the United States, housing 195,000 inmates in 122 facilities in 2016. Most inmates are awaiting trial or have been convicted of federal crimes.

The BOP employs approximately 39,000 staff members. In the more than 85 years that the BOP

has operated, there have been only eight directors. This position is appointed by the president but typically nominated by the attorney general. Sanford Bates, the superintendent of the federal prison system before the BOP was established in 1930, became the first director of the BOP. The second director was James V. Bennett, who served from 1937 until 1964. The first woman director was Dr. Kathleen Hawk-Sawyer, appointed in 1992. The first African American director was Charles Samuels, appointed in 2011.

Although the words used to describe the goals of the BOP have changed slightly throughout the years, its core mission has not. The BOP aims to protect the public by ensuring that federal offenders serve their sentences in facilities that are safe, humane, cost-efficient, and appropriately secure. This is achieved by employing staff members who are professional, well trained, and diverse. The BOP is also committed to providing correctional programming to assist inmates in leading crime-free lives when they eventually return to the community. This entry provides a brief description of the history of the BOP, the characteristics of the inmate population, the different security levels of the prisons, and some examples of the types of correctional programs offered.

History

Until the late 1800s, federal prisoners were held in state prisons and local jails. Congress passed the Three Prisons Act in 1891, creating the federal prison system under the U.S. Department of Justice. The first three federal prisons were United States Penitentiary (USP) Leavenworth in Kansas, USP Atlanta, and USP McNeil Island. Even though they were part of the same prison system, these prisons essentially operated independently from one another. Inadequate funding followed and many staff members lacked appropriate training. Following the passage of three new federal laws (including the 1918 Volstead Act), the federal inmate population doubled to over 4,000 inmates. Prisons became seriously overcrowded, leading to the opening of 11 additional prisons to house the population that had grown to 13,000 inmates by 1930.

In 1930, Congress passed legislation that officially created the BOP in order to create a more centralized prison system, improve record keeping, and create a classification system. Bates, the first director of the BOP, was a former commissioner of corrections in Massachusetts, the past president of the National Prison Association, a leader in prison reform, and an advocate of the medical model. Rehabilitation and individualized treatment were the primary goals of the medical model, which led to widespread use of parole and indeterminate sentencing. Under his direction, the BOP created its first classification system to designate inmates to the most appropriate prison. Low-risk inmates were sent to prison camps. More serious offenders were sent to the penitentiaries in Leavenworth or Atlanta. Other high-security inmates could be sent to USP McNeil, which provided an agricultural training program. Inmates with physical or mental health needs were designated to the medical referral center in Springfield, MO, which opened in 1933. Over the next 10 years, the BOP's inmate population continued to increase to approximately 24,000 inmates and remained relatively stable until 1980.

In the 1980s, with the political movement of "getting tough on crime," "truth in sentencing," and "the war on drugs," crime control initiatives, such as mandatory minimum statutes, *three strikes* laws, and a move to determinate sentencing, were introduced at the state level. At the federal level, the Sentencing Reform Act of 1984 established the U.S. Sentencing Commission, in order to create more consistency in sentencing. It established sentencing guidelines that increased sentence lengths for a number of federal crimes, especially drug convictions. Parole was also eliminated and the amount of *good time* (the reduction in time served for good behavior) an inmate earned while incarcerated was limited. These changes led to an explosion in the federal prison population from 24,000 in 1980 to almost 220,000 inmates in 2013.

Concerns about the disproportionate impact of sentencing policies on African Americans in particular led to reforms to the Federal Sentencing Guidelines for certain drug crimes. In 2014, the BOP experienced the first decline in the inmate population in 34 years. The number of inmates declined by 5,149 in fiscal year 2014 (October to

September). In the following year, there was another decline of 7,842 inmates. The BOP had been running at an overall capacity of around 138% for many years, so even with a substantial decline in the population, the prisons are still running over their rated capacities.

Federal Inmate Population

As of June 2016, there were a total of 195,383 federal prisoners. Of these, 158,883 inmates were incarcerated in BOP facilities, 22,670 federal inmates were managed in private facilities, and 13,830 inmates were in other facilities (such as halfway houses or home confinement). The majority of federal inmates are male (93%). The largest racial group is White (59%), followed by Blacks (38%), Native Americans (2%), and Asians (1.5%). The BOP reports ethnicity separately from race. There were 34% Hispanics and 66% non-Hispanic inmates. Compared to state prisons, the BOP houses a substantial portion of non-U.S. citizens (22%). Federal sentences tend to be longer than state sentences; approximately 72% of inmates are serving sentences ranging from 5 years to life, 24% are serving 1–5 years, and 4% are serving less than 1 year. The BOP also has more inmates convicted of drug offenses (46%) than state prisons and fewer inmates convicted of violent offenses (23%). Inmates convicted of property offenses account for another 12%, immigration offenses account for 9%, sex offenses for 8%, and miscellaneous offenses for 2%.

The Classification System and Types of Correctional Facilities

The BOP custody classification system incorporates several measures that are computed into an overall custody classification score (e.g., history of violence, history of escapes). After it is determined which security level an inmate will be assigned from the custody classification score, their medical and mental health needs are then separately assessed to determine the appropriate prison to which they should be designated. The medical classification system incorporates care levels ranging from one for healthy inmates to four for inmates who require the most services, typically in a hospital setting.

The federal prison system has five different security levels: high, medium, low, minimum, and administrative. The most restrictive settings are the high-security institutions, also known as *USPs*. These are designed to hold inmates who pose the greatest risk to other inmates, staff, and the general public. USPs' perimeters are highly secured and surrounded by walls or reinforced fences with guard towers, roving perimeter patrols, and extensive electronic surveillance. USPs have the highest staff-to-inmate ratio and have the most restricted movement of inmates. Medium-security prisons, or federal correctional institutions, have strengthened perimeters, such as double fences with electronic detection systems and perimeter patrols. There is a wide variety of work and treatment programs at federal correctional institutions, and inmates' movement is less restricted than in high-security prisons. Low-security federal correctional institutions also have double-fenced perimeters and roving perimeter patrols. Most of the housing units are dormitory style or cubicle housing. There are also strong work and programming components. Minimum-security institutions, also known as *federal prison camps*, can be stand-alone facilities or part of a complex that includes more restrictive prisons. The minimum-security camps have a relatively low staff-to-inmate ratio and limited, or no, perimeter fencing.

Administrative facilities are institutions with special missions. These administrative facilities include detention centers, medical centers, and the administrative maximum prison located in Florence, Colorado. The administrative maximum prison contains inmates who are considered to be extremely dangerous, violent, or escape-prone. There are 12 detention centers in the BOP system, and they are generally located in metropolitan areas. Detention centers house pretrial offenders. The BOP currently has five medical referral centers, hospitals for inmates with serious medical or mental health problems.

Correctional and Reentry Programs

Since its inception, the BOP has been dedicated to providing correctional programs for inmates ranging from education programs to mental health programs, faith-based programs, vocational programs, and leisure and wellness programs.

The education department provides a variety of services for inmates. Some programs prepare inmates to take the general education equivalency exam, while others provide English as a second language courses, adult continuing education, postsecondary education, and vocational training.

Correctional programs can be residential, in which all inmates who are participating in the program reside in the same housing unit. This housing unit is typically separated from the general population units and is based on a modified therapeutic community model. This environment creates a more positive culture and reduces the possibilities of negative peer influences. These programs are typically longer in duration (from 12 to 18 months) with more intense daily sessions than the nonresidential programs. They include sex offender treatment, the residential drug abuse treatment program (RDAP), and mental health step-down units.

The residential sex offender treatment program is for offenders who have a history of sexual offending, volunteer for treatment, and have a high risk of future offending. Institutions that offer the residential sex offender treatment program also have a higher proportion of sex offenders in their general population. This helps offenders feel more comfortable acknowledging their issues and seeking treatment. The RDAP is one of the largest correctional programs in the BOP. The RDAP is based on cognitive behavioral therapy, and participants are typically involved in half-day programming and half-day work, school, or vocational activities. The step-down unit program is designed for inmates who have a serious mental illness and lack the skills necessary to function in a general population housing unit. The goal of the program is to provide treatment in order to increase their daily functioning and minimize the need for inpatient psychiatric care.

The BOP also has numerous nonresidential programs that are shorter in duration. The inmates reside in general population housing units. One example of a nonresidential program is the 12-week-long drug abuse program. It is based on a cognitive behavioral therapy model and is conducted primarily in a group setting. The content addresses criminal lifestyles and provides skill-building opportunities in the areas of rational thinking, communication skills, and institution/

community adjustment. This program is for offenders who have short sentences, are transitioning to the community, do not meet the criteria for the residential program, or have had a positive urinalysis test. Inmates waiting to be enrolled in the RDAP may also take this program.

The BOP offers two formal faith-based programs for both residential and nonresidential settings, in addition to routine chaplaincy services in all of the prisons. The first is the Life Connections Program, which is an 18-month residential program that is located in four male prisons and one female prison. The second faith-based program is called *Threshold* and was created in 2008. It is the nonresidential faith-based reentry program and is offered in many federal prisons. The length of the program is 6–9 months with a session per week. Both programs are open to inmates of all faiths and add a spiritual component with workbooks and other course material based on the cognitive behavioral therapy model.

Lastly, Federal Prison Industries (UNICOR) was established in 1934 and is a self-sustaining operation, using the revenues from sales to support the program's operational expenses. Some of the goals of UNICOR are to provide job skill training, work experience, a sense of responsibility, and reduce recidivism. At the end of fiscal year 2015, there were 83 factories and approximately 12,000 inmates participating in the program.

FEDERAL PRISONS

Only one federal agency houses individuals convicted of crimes in U.S. federal courts: the Federal Bureau of Prisons (BOP). Other federal agencies contract and operate secure facilities for detaining individuals in pretrial status for violating federal laws. The two largest users of detention beds are the U.S. Marshals Service and Immigration and Customs Enforcement (ICE). The three agencies held almost 290,000 individuals at any one point during fiscal year (FY) 2015, and many more individuals passed through detention and prison beds operated by, or contracted for, these three agencies. At the end of FY 2015 (September 30), the BOP held 206,307 inmates and ICE had 39,082 detainees. The U.S. Marshals Service had 51,862 detainees per day on average for FY 2015. About 10,000 of the Marshals' detainees were held by the BOP and appear in the total for both groups. In addition to these three agencies, which focused primarily on civilians, the federal government operates prisons for those convicted in a military court for minor and major infractions. A small percentage of those individuals convicted of serious crimes in military courts are placed into federal prisons operated by the BOP. This entry discusses the history and use of prisons, jails, and detention centers by these U.S. federal agencies.

BOP

The BOP was created as an agency in 1930. As the only federal prison system holding civilians, it incarcerates adults found guilty in U.S. federal courts under the authority of the attorney general of the United States. Juveniles are rarely prosecuted in federal courts, and convicted juveniles are placed in contract facilities. The Three Prisons Act

of 1891 established three prisons as comprising the Federal Prison System. The original prisons were at Leavenworth, KS; Atlanta, GA; and McNeil Island, WA. Additional prisons were added and, in 1930, were all consolidated under the control of the BOP. At the time, there were 14 federal prisons holding 13,000 inmates comprising the BOP. A rapid period of population explosion in the BOP started during the 1980s with the establishment of determinate sentencing at the federal level (Sentencing Reform Act of 1984). For nearly two decades, the prison population increased rapidly, reaching a peak of 219,298 inmates in 2013. The population at the BOP declined in each year following 2013 due to changes in the sentencing laws, primarily for crack cocaine-related sentences, many of which were enacted retroactively.

Compared to other federal agencies, inmates stay in a BOP facility much longer than individuals at ICE and U.S. Marshals facilities. On average, inmates held in the BOP at the end of FY 2015 had a sentence of more than 10 years (141 months). During FY 2015, 43,987 inmates were released from the BOP, meaning that about 250,000 individuals were in the BOP at some point during FY 2015.

The BOP directly operates the vast majority of the facilities holding federal inmates. It contracted with the private sector to hold 24,336 inmates at the end of FY 2015. This accounted for 11.8% of the total number of federal inmates. Another 16,350 inmates were in facilities that are not typical federal prisons, with the majority in residential reentry centers and a sizable number on home confinement. This accounted for 7.9% of federal inmates under the custody of the BOP. This means that 80.3% of federal inmates were housed in a typical BOP prison.

Although the BOP holds inmates in different types of prisons designed to meet the risk posed by inmates, the private sector only holds federal inmates designated as low-security risk. The BOP security designations are minimum, low, medium, and high security. It operates one facility that holds inmates of the most severe custody risk, the administrative maximum security prison at Florence, CO. The Florence facility incarcerates domestic and foreign terrorists, as well as inmates who pose too great a safety risk at more typical

high-security prisons. The BOP also operates five medical centers at Butner, NC; Carswell, TX; Devens, MA; Lexington, KY; and Rochester, MN.

The BOP operates a federal transfer center in Oklahoma City. This facility is used for a number of purposes, including acting as a holdover destination for inmates not yet assigned to a permanent facility. The federal transfer center also holds parole violators who are moving back into BOP custody. Inmates moving from one BOP facility to another, or to court, also often end up at the federal transfer center in Oklahoma City.

Male and female inmates are typically housed in geographically separated prisons, although there are some facilities that provide separate housing for males and females at the same location. All federal detention centers accommodate both sexes, as do the metropolitan correctional centers at Brooklyn, NY; Guaynabo, PR; and Los Angeles, CA. The metropolitan correctional centers house both convicted inmates and pretrial suspects.

Females made up around 7% of the inmates housed by the BOP at the end of FY 2015. Most females were in prisons that were exclusively female. In addition to federal facilities that held inmates in a pretrial status, some female inmates were assigned to male prisons and served their time in prison camps. The prison camps are physically outside of the perimeter of the main facility. Camp inmates are often used to perform custodial duties for areas outside of the main facility.

Immigration and Customs Enforcement

ICE was created in 2003 by joining together parts of the U.S. Customs Service and the Immigration and Naturalization Service. ICE has an annual budget of around 6 billion dollars and is responsible for border control, trade, customs, and immigration. ICE is divided into two major operational segments: Enforcement and Removal Operations and Homeland Security Investigations. Enforcement and Removal Operations is the arm of ICE tasked with detaining and deporting illegal aliens. Homeland Security Investigations is the investigative arm of ICE with offices around the country and the globe. Homeland Security Investigations investigates all types of cross-border criminal activity.

ICE places arrestees in detention centers or jails across the country. It places detainees in 110 detention facilities. ICE operates some detention centers directly, but it also contracts with private sector companies and local government agencies to operate other detention centers. As of 2015, 62% of detention beds are operated by private prison companies, most notably CoreCivic (formerly Corrections Corporation of America) and GEO Group.

ICE detainees occupied 39,082 beds at the end of FY 2015. Because stays are short in ICE detention facilities, 325,209 individuals were held in an ICE detention facility at some point during FY 2015. The ICE total is larger than comparable figures for the BOP during that period. Although the numbers of BOP admissions and discharges are smaller than at ICE facilities, the length of stay in BOP facilities is much longer.

ICE facilities typically house male and female suspects separately, although there are three family residential centers where the sexes are comingled along with children. The intention of family centers is to provide a humane alternative for families awaiting extradition. Approximately 45,000 family members were placed in these facilities in 2016 from the apprehension of 77,587 family units nationwide.

U.S. Marshals

The U.S. Marshals Service is the enforcement arm of the federal court system. As such, the U.S. Marshals Service has responsibility for transporting and holding prisoners. They have responsibility from the time suspects are arrested until they are either acquitted or convicted in federal court. After conviction, U.S. Marshals are still responsible for transporting inmates across the United States.

The U.S. Marshals do not operate any jails. In several large cities (Honolulu, HI; Houston, TX; Miami, FL; Philadelphia, PA; and Seattle, WA), there are BOP-operated detention facilities that house pretrial inmates; these federal detention centers, along with metropolitan detention centers, account for a large proportion of the inmates held by the BOP for the U.S. Marshals Service. On an average day in 2015, according to the U.S. Marshals Service, the BOP held 9,774 detainees or 18.8% of the detainees in custody.

The majority of federal detainees on an average day were held in jails operated by or for local government agencies and private sector providers. Jails operated by state and local facilities held 31,603 detainees, or 60.9% of the total, on an average day. Privately operated jails held 10,248 (19.8%) detainees. The number of inmates held in private jail beds and federal jail beds was approximately the same. A small number of inmates, 237 on average, were held in miscellaneous locations, such as hospitals.

Detainees held by the U.S. Marshals Service do not cycle through as quickly as detainees held by ICE or as slowly as inmates held by the BOP. Inmates in pretrial status spend significant periods of time in jail before a court decision or bond release. As a result, the U.S. Marshals Service processed only 194,792 prisoners in 2015. This is much fewer processed, for example, than ICE, even though ICE had almost 20,000 fewer beds on any given day. The average stay for detainees under the custody of U.S. Marshals was 97.2 days.

Military Prisons

The U.S. military typically operates two types of prisons with very different functions. The first type of military prison is used to house enemy combatants, or prisoners of war, until hostilities cease. The best known prison of this type is the Guantanamo Bay detention camp located on the Guantanamo Bay Naval Base (Gitmo) in Cuba. It is run by the Navy and was established in 2002. Gitmo is a continuing source of controversy in the United States because it allows for the indefinite detention of individuals without due process.

The U.S. military, comprised of the Army, Marine Corps, Navy, and Air Force, had over 1.1 million personnel on active duty status in 2015. Military personnel fall under the civilian codes of their duty station, but they are also held to a code of conduct outlined in the Uniform Code of Military Justice (UCMJ). The UCMJ contains rules by which military personnel are expected to abide, and military members can be charged, convicted, and incarcerated for violating the UCMJ.

The second type of military prison is similar to the BOP's civilian prisons and addresses those guilty of UCMJ infractions. Although the goal of this type of military prison is to punish U.S.

military personnel, the intention is to return offenders to military service. Permanent facilities operated by the U.S. military are known as *disciplinary barracks* if they are run by the Army and *brigs* if operated by the Navy. There are both long-term and regional detention facilities, and the UCMJ specifies the appropriate type of facility. Long-term facilities, such as the United States Disciplinary Barracks at Fort Leavenworth, KS, hold service members from all military branches.

Permanent military bases for all of the armed services have small units where military personnel accused of an offense can be detained before being transferred to a location designated for detention purposes. For Army bases, these facilities are often called *guard houses* or the *stockades*.

The Army operates seven facilities, which are designed to hold 1,187 prisoners but held only 711 as of 2015. U.S. brigs are operated by the office of Corrections and Programs of the U.S. Navy. The structure is similar to that of the Army, with a distinction between long-term and regional brigs.

FEMALE OFFENDERS

Girls and women account for between 2% and 9% of the world's incarcerated population. Although these numbers may not seem

particularly distressing, it is necessary to emphasize that, worldwide, the female incarceration rate increased 50% between 2000 and 2015. This increase is almost 3 times higher than the corresponding rate for males.

Historically, scholars and correctional agencies have intentionally or unintentionally ignored female offenders. Further, early explanations of female criminal conduct were sexist, suggesting that men commit crime because of external causes such as poverty or peer pressure, whereas women commit crime because of internal causes such as faulty biology. However, this is no longer the case. In the early 21st century, scholars who study crime began to take an active interest in understanding why female criminal conduct occurs, reoccurs, and how it should be prevented and treated. Similarly, correctional agencies worldwide are slowly adopting female-centered philosophies grounded in the assumption that females (girls and women alike) are different from their male counterparts.

This entry first reviews two prevailing theories of female criminal conduct: (1) a gender-neutral theory of crime that is purported to apply equally to both sexes and a (2) female-specific theory, developed specifically for girls and women. Next, it reviews key risk and need factors responsible for the initiation and maintenance of female criminal conduct and discusses how these factors are incorporated into correctional interventions. Finally, this entry offers some recommendations for research and practice in the field of female offender rehabilitation.

Theories of Female Criminal Conduct

There are various theories of criminal conduct, and a few focus explicitly on female crime. This section briefly reviews two theories of crime and their applicability specifically to girls and women.

Pathways Theory

Pathways theory was written specifically to explain female criminal conduct. It states that girls and women initially start engaging in criminal conduct largely because of adverse events, such as childhood maltreatment (e.g., abuse and neglect), poverty, or dysfunctional relationships with caregivers or intimate partners. Pathways theorists

further hypothesize that females cope with these adverse events by running away from home, abusing drugs and/or alcohol, developing anxiety and/or depression, or simply by doing whatever it takes (e.g., transporting drugs across the border to please a partner) to maintain the dysfunctional relationship. In turn, these coping mechanisms lead to criminalized survival methods, such as prostitution, drug use/dealing, or robbery.

The pathways perspective is a feminist-inspired model written in response to years of male-dominated scholarship that explicitly or implicitly discounted the female perspective. Noteworthy, the pathways model of female criminal conduct is as much about theory as it is about method. In particular, pathway theorists have developed theories of female offending using methodologies that intentionally give girls and women a voice. Accordingly, feminist pathways researchers have typically used qualitative methods of inquiry to study female offenders. These methods are usually interview based and consequently give girls and women an opportunity to tell their stories in their own words.

As of 2016, there were several (about 30) different studies that examined female criminal conduct through the lens of pathways theory. Collectively, quantitative (the study of numbers) and qualitative (the study of words) research has clearly found that various forms of victimization (e.g., sexual, emotional, and physical abuse; neglect; and witnessed violence), family disruption, running away, substance abuse, depression/anxiety, and poverty are key themes in the lives of women and girls who have committed crime. However, more research is needed because much of the existing research has failed to incorporate detailed questions related to the nature and context of victimization (e.g., sexual abuse by a trusted adult over a prolonged period of time versus witnessing violence perpetrated between strangers). As well, research that explicitly compares males and females is needed to determine the extent to which the pathway theory is truly unique to females.

Personal, Interpersonal, Community-Reinforcement (PIC-R) Theory

The PIC-R theory is a general model of criminal behavior that aims to explain individual

differences in criminal behavior in both males and females. PIC-R is largely built upon two preexisting theories of criminal behavior: social learning theory and personality (self-control) theory. Social learning theory hypothesizes that both males and females learn to commit crime through the same mechanisms, such as differential reinforcement. One woman, for example, continues to commit crime because most of her friends support (i.e., reinforce), rather than discourage, her criminal activity. In contrast, self-control theory focuses on personality traits and the environment. Self-control theory hypothesizes that males and females are more likely to commit crime when given the opportunity to do so and that they possess impulsive and sensation-seeking personality traits. These impulsive and sensation-seeking personality traits foster a tendency to seek short-term gratification (e.g., “I can steal a new iPod now”) rather than a consideration for long-term consequences (e.g., “I will end up on probation for one year”).

PIC-R categorizes criminal risk factors into four domains for males and females alike: situational, personal, interpersonal, and community. The situational domain includes factors that can change rapidly, such as opportunities (e.g., temptations), stressors (e.g., a single mother who just lost her job), facilitators (e.g., sudden psychotic state), and disinhibitors (e.g., acute drunkenness). In contrast, personal factors are an individual’s characteristics that typically do not change without intervention. They include things such as criminal thinking styles (e.g., “crime is ok,” “insurance covers what I steal”) and antisocial personality features (e.g., cold/callous, lacking remorse, impulsive, manipulative). PIC-R also classifies gender and having a long and varied criminal history as personal risk factors, albeit as static, or nonchanging, factors. Although gender is classified as a personal variable that shapes both the person and the immediate situation, it is not central to the model. Interpersonal factors include variables such as criminal friends and family/marital dysfunction (e.g., having an intimate partner who is also criminal). Lastly, the community dimension encompasses factors such as the quality of one’s neighborhood (e.g., a person who resides in a high crime neighborhood is more likely to engage in crime than one who resides in an affluent neighborhood). In sum, PIC-R argues

that, irrespective of gender, as the number of these factors increases, so does the probability that the rewards for doing crime will exceed the costs. Ultimately, it is variations in the reward-to-cost ratio that explains why one person engages in crime and another does not.

There is considerable research in support of the PIC-R as a general theory of crime for males and females alike. Even some feminist scholars have acknowledged that these seemingly gender-neutral perspectives have merit in understanding female criminal conduct. For instance, it has been suggested that social learning and related theories such as PIC-R may help explain why males are more likely to engage in crime in the first place; males are more likely to associate with antisocial peers than females because boys have greater access outside the home, providing more exposure to negative peers, whereas girls have less access due to more supervision and control in the home.

Gender-Informed Risk Factors

Through socialization, biology, or a combination of the two, differences in gender yield different life experiences for girls and women, compared to boys and men. The term *gender informed* reflects these between-group differences; when referencing a gender-informed concept for girls and women, it means that gender is a preeminent consideration. For example, a gender-informed teaching method for females would be one that yields relatively better results for girls and women; it is one that females are more responsive to than males because in its development, gendered (female) considerations were taken into account. In contrast, a *gender-neutral* concept is one that makes no consideration of gender; in form and measurement, the concept operates in the same manner for males and females alike. This section considers criminal risk factors and, more specifically, gender-informed risk factors.

Risk factors are variables that, when present, increase the likelihood that criminal behavior will occur. They help predict if criminal behavior will occur at some future date. Risk factors are generally described as either static or dynamic. *Static* risk factors are constant and unchanging or change only in one direction (e.g., age, criminal history). *Dynamic* risk factors are characteristics

of the offender or his or her situation, which are changeable, with changes associated with changes in the likelihood of reoffending (criminal recidivism). As such, dynamic risk factors (also called *criminogenic needs*) are considered promising targets for correctional intervention.

Various studies have shown that some of the best risk factors associated with criminal recidivism (for males and females alike) include static risk factors such as current age, number of previous offenses, age at first arrest, criminal versatility, poor parental supervision, and early onset of behavioral problems (e.g., lying, cheating, stealing before age 12 years). Static factors, although good predictors of future crime, are not amenable to treatment.

The gender debate with respect to risk factors lies mainly in the area of dynamic risk. This is because correctional programming targets dynamic risk factors, and these interventions must be informed by sound empirical research. Until the late 1990s or early 2000s, the vast majority of research had been conducted using male-only, or predominantly male, samples. Feminist-inspired researchers have strongly questioned the scientific merit of assuming that research conducted on male offenders will naturally generalize to female offenders. Nonetheless, a large body of male-based research has produced consistent findings: Correctional programs reduce reoffending by, on average, 10%. Further, through foundational meta-analytic research published in 1990, Don A. Andrews and colleagues provided a convincing demonstration of how programs adhering to now widely accepted principles of effective correctional intervention (risk, need, and responsivity) show the most promising correctional results yielding reductions in recidivism in the range of 30%. Andrews and colleagues' original findings have been supported by a large number of male-based studies, and the risk-need-responsivity model is universally accepted as a best practice in correctional programming.

According to Andrews and colleagues, the most promising treatment targets include: antisocial attitudes and feelings; antisocial associates; poor self-control, self-management, and/or problem-solving skills; substance abuse problems; lack of education and/or vocation; lack of familial ties or dysfunctional family relationships; and poor use

of recreational or leisure time. The general acceptance of these factors as criminogenic needs is based on a considerable body of research.

As noted, the appropriateness of these promising treatment targets for girls and women has been challenged in the correctional literature. The skepticism comes, in part, from the fact that the supporting research is based on samples of male offenders. As such, some advocate for gender-specific assessment and intervention for girls and women. These authors argue that certain other needs, more prevalent among justice-involved girls and women (e.g., parenting stress, a history of trauma, adverse social conditions, and mental health problems), can also impact response to treatment and correctional outcomes. This point of view is supported by work demonstrating that many girls and women have gendered pathways into the criminal justice system.

Correctional Interventions

To respond to this gap in service for girls and women, the latest generation of correctional interventions is labeled gender informed or gender responsive. Although many of these interventions incorporate traditional program elements, they also consider needs that are particularly salient to females and are founded, at least in part, on pathways perspectives and other theoretical models, such as *relational-cultural theory* (a perspective that underscores the centrality of relationships in women's lives) and strength-based approaches. Gender-informed approaches are *trauma informed* (consider the impact of trauma in lives of girls and women) and consider the gendered context, including pathways associated with female offending.

In 2016, Renée Gobeil, Kelley Blanchette, and Lynn Stewart conducted a systematic summary (a meta-analysis) of 37 individual studies examining whether correctional interventions for women offenders are effective in reducing recidivism. The authors also explored whether gender-informed interventions differ from traditional (i.e., gender-neutral) programs in their effectiveness. The results showed that women who participated in correctional interventions had 22–35% greater odds of community success than nonparticipants. In other words, correctional interventions for women are

at least as effective as the published rates for men. When analyses were limited to studies of higher methodological quality, gender-informed interventions were significantly more likely to be associated with reductions in recidivism.

One study that looked at correctional programs for youth offered further insight into what works well for girls. Specifically, it showed that gender-informed programming for youth in secure detention was associated with a lower risk of recidivism only for girls with gender-specific risk factors. The authors concluded that incarcerated girls require different approaches depending on their histories of trauma and associated mental and physical health issues. Specifically, although girls who followed gendered pathways into detention benefited from gender-informed programs, girls without such needs gained more from traditional (gender-neutral) programming. Similar findings were noted in a study exploring correctional outcomes for women offenders who participated in gender-informed substance abuse treatment. Researchers looked at whether a history of sexual or physical abuse would have any impact on the effectiveness of substance abuse treatment for two groups: (1) women substance abusers who were randomly placed in a gender-neutral substance abuse program or 2) women substance abusers who were randomly placed in a gender-informed substance abuse program. Results showed that those who had reported having experienced abuse and who were treated with gender-informed interventions had significantly better outcomes compared to those who reported abuse and were treated in the gender-neutral program group. For women who had no history of sexual or physical abuse, the gender-neutral program was comparable to the gender-informed program (e.g., likelihood of relapse into substance abuse was about the same). The authors concluded that women offenders who have experienced prior abuse may benefit most from interventions that are trauma informed and gender informed.

Rehabilitating Female Offenders: Past, Present, and Future Advancements

In the mid-1980s, Robert Ross and Elizabeth Fabiano coined the term *correctional afterthoughts* in reference to female offenders. In that

era, the designation appropriately reflected the lack of research to guide interventions for justice-involved girls and women. Indeed, until the 1990s, girls and women were rarely included as research participants, and correctional practice simply mirrored what was done for boys and men.

In the 1990s, as researchers began to place greater focus on what works in terms of offender treatment, girls and women were more often included in research studies, in attempts to ensure that evidence-based interventions were gender neutral. Notwithstanding those efforts, the research was predominantly male based, and results were rarely disaggregated by gender. There were few attempts to consider or study alternatives to the male model. Instead, the approach was like force-fitting correctional services for girls and women into a model built for males. Accordingly, skeptics still argued that correctional interventions were male based and not appropriate for females.

The 21st century has brought with it a greater understanding that gender matters and, consequently, a growing body of research to inform correctional policies and programs for girls and women. Pathways into the criminal justice system suggest that female offender populations have multiple needs, most often including substance abuse problems, experiences of trauma, family dysfunction, and mental health issues. Accordingly, modern-day programs for female offenders target multiple need areas, either holistically in an integrated program or sequentially through multiple programs.

Researchers continue to make impressive gains in the development and evaluation of risk assessment tools developed specifically for women. Gender responsive treatment programs continue to be developed. On the international stage, in 2010, the United Nations declared that all incarcerated women should be treated in accordance with the Bangkok Rules. By unanimously endorsing the Bangkok Rules, the 193 member countries acknowledged that women in the criminal justice system have gender-specific characteristics and needs that require a gendered approach. This is a tremendous sign of progress in research and practice in the area of corrections for girls and women.

Looking Forward: Recommendations for Research and Practice

Although it is clear that great gains have been made for gender-informed corrections for girls and women, there is still opportunity for improvement. Going forward, it is suggested that theories should steer away from being gender neutral and become gender informed. This involves gendering (or operationalizing) core constructs in such a manner that readily accommodates female-specific factors, such as the importance and centrality of positive healthy relationships. In their efforts to develop gender-informed theories (or adapt existing theories), social science theorists must be vigilant to avoid stereotypes based on gender. As such, it will be a challenge for progressive theorists to develop and apply their work in a manner that is informed by gender, yet free of stereotypic schemas.

As researchers continue to develop assessment models for female offenders, they should consider assessment tools that are gender informed and built from the ground up for the specific population to which they will be applied (in this case, girls and women). Many static risk predictors are *gender invariant*, meaning that they help to predict outcomes for both males and females. However, there are also factors that are more relevant to girls and women, and these should be carefully considered when assessing females.

Finally, it is important to recognize that females represent a diverse group of correctional clients. They range in age, culture, ethnicity, their pathways into the criminal justice system, needs, abilities, and strengths, to name a few. A one-size-fits-all approach will not work. Although integration of gender-informed factors is critical, those working with females as correctional clients must also tailor their services to the individual.

FEMALE OFFENDERS: CONTROVERSIES IN ASSESSMENT, TREATMENT, AND MANAGEMENT OF

The number of women involved in the criminal justice system in the United States has grown exponentially over the past several decades. With this increase, key dilemmas and questions have shaped practices of assessment, treatment, and management for this population of women. Given that a majority of these practices are based on male offenders, attention has been given to exploring gender differences in offender populations and the subsequent role of gender in these practices. This entry discusses gender differences in offender populations as well as the assessment, treatment, and management of female offenders.

Gender Differences in Offender Populations

Significant differences between men and women involved in the criminal justice system have been highlighted as rationale for considering gender in relation to criminal justice practices. National data show gender differences in the rates of involvement in the criminal justice system and, in

particular, types of crimes. Women comprise approximately only 25% of all arrests, 25% of adults on probation and parole in the community, and 5–7% of the prison population. Although almost 75% of women are convicted of nonviolent crimes, over half of men are convicted of violent offenses. Even within the category of violent offenses, men and women differ in types of violent crimes (e.g., sex offenses, murder, robbery). Women's descriptions of their crimes more often include motivations of trying to survive severe economic marginalization and escape violence from partners than men's descriptions.

In addition, female offenders enter the criminal justice with significant rates of specific concerns and risk factors. They are more likely to report the following factors than male offenders:

- status as primary caregivers of minor-age children
- childhood history in a single-parent household
- history of an incarcerated parent
- low educational attainment
- experiences of poverty with little or no employment history
- experiences of multiple forms of abuse and victimization (especially sexual victimization) in childhood and adulthood
- substance use and mental health disorders (often as co-occurring)
- multiple physical health concerns that are often under- or untreated

Approximately 75% of incarcerated women have mental health problems, versus 55% of men in state prisons. Given women's high rates, these factors have been targeted as areas for assessment and treatment as well as influencing management needs for female offenders.

In addition, the aforementioned factors have been identified as key aspects of female pathways to crime in different ways than male pathways to crime. For example, in comparison to men offenders, women are more likely to have histories of substance use, including histories of polysubstance use, early start of using, and more frequent use. They also specifically cite substance use as a coping strategy for experiences of trauma and adversity. Women describe their crimes as related to drug use and more often report current use

when arrested than men. Across studies, women involved in the criminal justice system have common trajectories into criminal justice involvement. These trajectories include histories of living in marginalized and disadvantaged communities, growing up in families with violence and incarcerated members, experiences of sexual and physical victimization in both childhood and adulthood (often within primary relationships), extreme poverty and unemployment, and resulting mental and physical health problems.

Most of the research about women's pathways into crime focuses on the pivotal and central role of adversity and trauma, especially in regard to the cumulative nature of these experiences and the significantly higher rates of victimization that women experience, which is referred to as *gendered violence*. These experiences also occur within a gendered context. For example, women often experience criminal justice involvement for their coping and survival strategies (e.g., running away from sexual abuse occurring at home, which results in arrest as a teenager). Also, race, class, and gender have been deemed a triple jeopardy for women with multiple forms of marginalization and disadvantage, contributing to the overrepresentation of women of color in the criminal justice system. Emerging theory also posits that women involved in the criminal justice system are denied forms of capital across their life courses, which contributes to further disadvantage and their involvement.

Assessment

Upon entry into the criminal justice system, offenders are assessed for several factors (risks and needs). Often, this occurs with standardized tools. These assessments are used to establish the offender's risk level for recidivism and/or misconduct behavior while incarcerated. For example, assessment tools allow for determining an offender's risk score in order to determine custody level while incarcerated or supervision level if the offender is facing probation or parole. Assessment tools are used across time points of involvement in the criminal justice system, including pretrial detention release, sentencing, within prison, and during parole board decisions. Likewise, the assessment process can guide and result

in a treatment plan to address specific risk- and need-based factors with the purpose of reducing criminality-related behaviors and preventing poor criminal justice outcomes. Therefore, assessment tools are a primary component of the criminal justice system.

Assessment tools have changed over time to reflect expansions in both knowledge and perceptions around criminal justice. Initial assessment tools (often called *first generation*) mainly focused on capturing *static factors* (factors that do not change over time). Assessment tools have transformed to include both static factors and *dynamic factors* (those that can change). These factors have been found to be predictive of recidivism and other criminal justice outcomes. Examples of static factors are prior offenses and offender's relationship to the victim. Examples of dynamic factors are education, employment, and physical health needs, in addition to antisocial attitudes, criminal peers, and personality concerns. Framing dynamic factors as *needs* posits these factors as areas for intervention. Assessment instruments that incorporate both risks and needs are typically related to the Risk-Needs-Responsivity model that does not explicitly consider gender.

Although considered gender neutral, these tools have typically been tested exclusively with men offenders. Perspectives in support of these gender-neutral tools posit that risk factors, especially those that are dynamic, are similar for both men and women. Given the extensive history and research base for these older assessment tools, this perspective stresses that there is little to no need for additional or specific tools for female offenders. Likewise, research on using these tools with female offenders includes mixed results showing both predictive validity for women and a lack of such validity. For example, a meta-analysis of assessment tools specifically for institutional violence and violent crime recidivism found that effect sizes could only be determined for male offenders not female offenders due to the sample composition of existing studies. In contrast, some studies have found that a specific assessment tool, the Level of Service Inventory-Revised, has shown an ability to predict female offenders' behaviors during incarceration and reentry. Researchers have also questioned the quality of the predictive accuracy of this tool, if

the accuracy is similar to the predictive power for male offenders, and if it is best for guiding practices with female offenders. One major concern related to assessment and gender is that using assessment tools that have not been tested with, or designed for, women leads to the overclassification of female offenders. Thus, women are erroneously put into higher custody levels (e.g., more severe and restricted levels) even though they engage in fewer acts of serious misconduct behavior than men in the same custody level.

Likewise, assessments that look at current risks and needs for offenders do not typically take into account *gender-responsive factors*, which are those factors disproportionately found for women. In addition, assessment tools do not address and account for the interconnections between trauma, substance abuse, and mental health that are common for female offenders. Thus, another perspective has included testing risk and need factors in conjunction with gender-responsive factors. For example, an assessment tool called the *Correctional Offender Management Profiling for Alternative Sanctions* (often referred to as COMPAS) has demonstrated reliability and moderate to strong predictive accuracy with male and female offenders. However, researchers have also added gender-responsive items to this measure in order to enhance it specifically for female offenders. Preliminary research suggests that both traditional predictors and gender-responsive factors are predictive of criminal justice outcomes (prison misconducts, recidivism, and offense type) but have nuanced patterns (e.g., child abuse as predictive of specifically prison behavioral outcomes). These results have been found for women in prison as well as replicated with those on probation and parole.

Although some researchers advocate for gender-responsive assessment instruments, one major concern is how gender-responsive assessment may be used and, in particular, the question of whether gender-responsive assessment tools will lead to further detrimental criminal justice experiences for women, such as higher custody levels or longer stays in prison. Thus, some scholars have posited that, instead of focusing solely on gender-responsive assessments, correctional settings may need to be reformed to become gender-responsive environments that influence specific

practices. Principles of gender-responsive practice apply to the assessment process and include the use of instruments normed with women, a strengths-based approach and nonjudgmental attitude, identification of the complex factors associated with substance abuse for women, and a process that is in alignment with a woman's language, literacy level, and cognitive functioning. Also, assessment should be considered ongoing, especially as women develop a therapeutic relationship, participate in treatment opportunities, and perhaps become clean and sober while involved in the criminal justice system.

Treatment

Similar to assessment debates, a range of perspectives exist about how to, if at all, consider gender in regard to treatment models for offenders. Offenders are often separated into different correctional facilities and supervision sites based on gender. This difference in correctional facilities has translated into gendered programming. For example, in regard to educational opportunities, legal disputes have focused on the unequal and inequitable opportunities for incarcerated men and women. For example, men are typically offered auto mechanics and other skill-based training opportunities, and women are offered cosmetology.

Gender differences between male and female offenders have been deemed rational for differences in treatment. Women commonly need mental health services while involved in the criminal justice system. For example, between 50% and 90% of incarcerated women report clinically significant depressive symptoms. A national study found that 73% of women in state prisons had a mental health problem; this is 6 times higher than the rate of 12% for women in the community. However, treatment for women in prison is rare and often insufficient. National estimates indicate that only 24–34% of prisoners with a mental health concern receive mental health care. Researchers have suggested that women's prisons often lack these types of services (more so than men's prisons).

Although limited services exist for incarcerated women, the number of evidence-based interventions has increased for women in correctional

settings in the past 20 years, offering more options for treatment. However, the area of intervention development and testing still remains a vital area for expansion in research and practice. The most common goal of interventions for female offenders is reducing recidivism rather than primarily psychological health. Specific concerns are the general lack of research and investment in suicide prevention programs for women in prison and the overreliance on male-based, and overwhelmingly male-tested, treatments.

Gender-responsive and trauma-informed services have been strongly advocated for female offenders. Gender-responsive interventions focus on empowerment, improving problem solving and self-image, and self-efficacy, based on understanding the pathways to crime that are common for women are based on their high rates of victimization, mental health distress, and substance use disorders. In particular, treatment that incorporates women's histories of trauma and abuse has been stressed as not only more relevant for women but also more efficacious in terms of outcomes. Female offenders with histories of sexual and/or physical abuse who undergo gender-responsive substance abuse treatment have significantly better outcomes for depression and substance use than women who have abuse histories but receive nongender-responsive treatment. Thus, treatment models that are gender responsive (e.g., attentive to women's need for childcare, parenting support, building self-efficacy, assistance in finding housing and employment, physical and mental health care) and trauma informed are especially advantageous for female offenders.

Management

Within correctional settings, the supervision of female offenders has historically been characterized by some scholars as paternalistic. In general, scholars posit that inmates face the risk of developing a learned helplessness while within correctional facilities due to the rigid and highly structured environment. Likewise, historically, female offenders have been viewed as more emotionally demanding than men, and this perception persists as correctional officers cite women's emotionality as a distinct, gendered supervision challenge. Concerns have also been raised about how

correctional settings have caused women additional trauma and difficulty (e.g., sexual abuse by correctional officers, further reduction of self-esteem and self-efficacy). Thus, some scholars have posited that, instead of focusing solely on gender-responsive assessments or treatment, a wider change could be considered. Correctional settings may need to be reformed to become gender-responsive environments. Six guiding principles have been outlined for correctional management, supervision, and treatment of women offenders, including creating a safe and respectful environment, programs and policies to foster healthy relationships, and improving women's socioeconomic status.

For probation and parole, traditional models of supervision do not consider the role of gender. This traditional model includes the following factors:

- a supervision goal of moving women quickly to a lower risk level or off of supervision
- the role of the correctional officer as implementing the plan placed by the judge
- no consideration of correctional officer's gender, equal or same treatment of male and female offenders
- connecting offenders with substance use and mental health treatment options

This model has been critiqued as insufficient for the needs of female offenders. Gender-responsive community supervision, in contrast to traditional supervision models, focuses on the following:

- addressing the main causes of women's involvement in the criminal justice system, in addition to completion of supervision requirements
- encouraging pairing female offenders with female officers, with attention to officer expertise and the women's needs
- an active role for the officer in advocating for, and shaping, the judge's and court's responses to the female offender, and using wrap-around services

As with the domains of assessment and treatment, there is some fear that gender-responsive

services for management and supervision will result in increased punitive control over women offenders. These debates speak to larger issues about the role of the criminal justice system and balancing social control and ideas of public safety with concepts of justice, prevention, and social change.

FEMALE OFFENDERS: GENDER DIFFERENCES IN CRIMINAL OFFENSE CHARACTERISTICS

Official statistics clearly demonstrate an overall gender gap in crime, whereby males account for the vast majority of offenders. Moreover, gender differences emerge in the contextual details of particular offense types. The term *offense gestalt* has been used to capture these nuanced gender differences, encapsulating factors such as the offender-victim relationship, the degree of victim harm, and the underlying motivation that seemingly catalyzed the offense. Aside from prostitution, female representation is greatest in the realm of minor property crimes motivated by perceived economic necessity. When women do commit violence, these acts tend to be less serious in nature than those committed by their male counterparts. Rather than target strangers or casual acquaintances, women's use of violence is typically relational in nature and directed toward familial or intimate partners, with motivations ranging from self-defense to the expression of anger and frustration. The objective of this entry is to identify and explain gender differences that characterize both violent and nonviolent forms of criminal behavior. Many of these gender differences are consistent with broader theoretical perspectives hypothesizing that what matters most to women is establishing and maintaining meaningful relationships over the pursuit of individual goals.

Gender Differences in Violent Crime

The gender gap in crime is most pronounced in the context of serious violent crimes such as homicide, sexual assault, forcible confinement, robbery, and aggravated assault. Compared to males, the vast majority of justice-involved females perpetrate offenses that are relatively minor in severity (e.g., nonviolent offenses like fraud and drug-related crime). When girls and women commit violent offenses, these incidents typically involve common assaults of marginal severity that occur in school or domestic settings. Indeed, the most frequently reported convictions of violent crime perpetrated by women in the United States have been linked to

domestic violence. In comparison with men, who are more apt to direct violence toward strangers and/or acquaintances, women are more likely to have a relationship with the target of their aggression, either in the form of a close relative or an intimate partner. The nature and typical targets of female-perpetrated violence are consistent with *relational-cultural theory*, a prominent feminist-derived perspective that underscores the centrality of relationships in the lives of women (in other words, women grow through and toward relationships and relationships are the source of meaning and empowerment in life).

Intimate Partner Violence

Despite some debate on the relative prevalence of female- versus male-perpetrated intimate partner violence (IPV), there is evidence to suggest that relative to women, men are significantly more likely to engage in serious forms of aggression toward a partner, including the perpetration of sexual assault. Compared to men, women convicted of IPV are half as likely to recidivate with a new domestic violence offense and are significantly more likely to be the victim in subsequent domestic violence reports.

Several family violence scholars have argued that IPV committed by women is primarily defensive in nature. Beyond self-defense, however, other commonly cited motivations reported by women include the expression of anger and frustration, a reactive response to long-term abuse, and an attempt to gain a partner's attention. Although male motivations for the commission of IPV can also be varied, domination and coercive control are those most frequently cited in the literature.

Intimate Partner Homicide

Intimate partner homicides frequently occur against a backdrop of domestic violence, which can be either unidirectional or bilateral in nature. The reported proportion of female-perpetrated spousal homicides has ranged from 20% to 40%. Notably, important gender differences emerge in both the motivation and context of intimate partner homicide. A male perpetrator is likely to have subjected his female partner to prior physical abuse and is most likely to commit spousal

homicide following an actual or imminent separation. In fact, a woman's decision to leave the relationship is the catalyst for her partner subjecting her to lethal violence in nearly half of spousal homicides committed by males. Typical motives articulated by men who have killed their partners include possessiveness and jealousy, suspicion over a partner's fidelity, and as indicated earlier, anger over the threat of separation. Women, in contrast, are more commonly motivated by self-defense, by a desire to thwart future harm and/or as a reaction to sustained victimization.

Filicide

Although it has been reported that mothers and fathers account for about equal proportions of homicides against their children (including biological and stepchildren), mothers are more likely to have killed children under the age of 7 years. The few available studies on filicide indicate that male-perpetrated killings are largely motivated by (a) retaliation (e.g., anger for spouse projected onto child), (b) jealousy or rejection by the victim (e.g., uncertain paternity; perception that spouse is giving the child too much attention), and (c) discipline (e.g., child killed during the course of punishment).

In contrast, motives for mothers who kill their children are complex, ranging from mental illness to financial difficulties, and vary depending upon the age of the child. Neonaticide (murder of a child during the first 24 hr of life) is most commonly committed by young mothers who have substance abuse issues, financial problems, and below-average intelligence; this form of filicide is often preceded by a denial of pregnancy. Infanticide (murder of a child within the first year of life) also tends to be committed by very young mothers, but in this group, women are more likely to display intense anger and impulsivity. Lastly, filicide involving older children tends to be perpetrated by women with a long history of mental illness and self-directed violence—often catalyzed by their own experience of childhood abuse.

Stalking

Stalking has been defined as persistent (at least 4 weeks) and repeated (10 or more) attempts to intrude on or communicate with a victim who

perceives said behavior as unwelcome and fear provoking. While community-based studies indicate that women comprise just over 10% of stalkers, rates ranging from 17% to 33% have been reported in forensic mental health settings.

No significant gender differences emerge among stalkers with respect to mental health diagnoses, where prevalence rates for delusional disorder, mood disorders, and personality disorders are high among both male and female stalkers. However, according to research conducted by Reid Meloy and his colleagues in 2011, female stalkers are significantly less likely than their male counterparts to have a history of criminal or violent behavior (18% vs. 43%); similarly, women are less likely to perpetrate violence in the context of stalking. Rather than targeting previous intimate partners as is common among male stalkers, females will more often fixate upon public figures or contacts with whom they have had a professional relationship (e.g., mental health practitioner, teacher, legal counsel). With respect to primary motivation, women are most commonly classified as *intimacy seekers* (45% of females vs. 25% of males), where the ultimate goal is to establish a close and loving connection with the victim (as opposed to motivations that are purely sexual, based on revenge, or incompetent attempts at courtship). While 90% of male stalkers target female victims, victims of female stalkers are more evenly distributed by gender.

Serial Homicide

While Ted Bundy, Jeffrey Dahmer, and John Wayne Gacy are chillingly notorious names, few readers may be familiar with the names of Nannie Doss, Genene Jones, and Dorothea Puente. Albeit rare, the latter are female serial killers, capable of the most extreme forms of violence. Drawing upon data from the last two centuries, it has been estimated that about 16% of serial homicide offenders are women. Serial homicide has been operationalized as the sequential killing of three or more human victims over a period exceeding 30 days, characterized by an emotional *cooling off* period between each event. While the preponderance of single homicide offenses are extrinsically motivated by a variety of functional factors running the gamut of monetary gain, revenge, and

victim precipitation, serial homicide is etiologically distinct. Typically premeditated, the killing itself is generally considered intrinsically pleasurable or reinforcing to the offender.

Among serial homicide offenders, gender differences are pronounced in the areas of motivation, victimology, and modus operandi. Male serial killers typically aim to exert ultimate power and control over their victims, a motive that is often inextricably linked with sexual gratification. Women's motives, although arguably hedonistic as well, tend to exclude the sexual component; some frequently cited motives include monetary gain (i.e., "Black Widow"), power or control (i.e., "Angel of Death"), or histrionic attention seeking. Relatedly, nearly 40% of female serial killers experience some form of mental illness ranging from Munchausen's syndrome by proxy, schizophrenia, and major depression.

The typical male serial killer will target strangers (usually young women) and use direct or hands-on methods to perpetrate his crimes (e.g., strangulation, stabbing). In contrast, over 80% of the female serial killer's victims are known to her, with the most common targets being family members or acquaintances. According to a 2015 study of 64 female serial killers who operated in the United States between 1821 and 2008, Marisa Harrison and her colleagues determined that 40% were health-care professionals and over 20% occupied direct caregiving roles like babysitter and stay-at-home mother/wife. Their broad range of victims—including children, spouses, the infirm, and/or older adults—consists of both males and females who are either in their care or in otherwise vulnerable positions. Women tend to use less conspicuous and less direct methods of killing (e.g., poisoning) and are less geographically mobile than their male counterparts.

Gender Differences in Nonviolent Crime

Drug Offending

Substance abuse plays an important role in the etiology of female offending, particularly given its pervasive presence in the criminal subculture. It is argued that many girls enmeshed in *the street life* commit crimes to support their drug habit or engage in criminal acts as a result of their intoxicated state. Female drug users are more likely than

their male counterparts to have been introduced to this lifestyle by the direct influence of a romantic (male) partner.

Substance abuse is a strong predictor of recidivism for both men and women. However, there is evidence to suggest that there may be gender differences in the etiological function of this factor. Among women in particular, there is a high co-occurrence of substance abuse, family-based trauma, and mental health issues. As such, women's abuse of drugs and alcohol is commonly grounded in a desire to self-medicate and cope with complex trauma. In contrast, males are more likely to engage in drug use to seek pleasurable effects and/or in response to peer pressure. With respect to direct involvement in the drug trade, women are typically initiated into these organizations through their associations with male partners and are commonly relegated to lower positions (e.g., courier); males, in contrast, are more likely to occupy positions of power.

Property Crime

The gender gap narrows considerably in the perpetration of property crime. For example, according to the 2014 Uniform Crime Reports, females accounted for 43.2% of individuals arrested for larceny-theft (vs. 56.8% for males). In a seminal investigation conducted in 2015, Darrell Steffensmeier and his colleagues examined gender differences in larceny, fraud, forgery, and embezzlement (LFFE offenses). Their results suggest that the vast majority of both male and female perpetrators of LFFE offenses commit relatively minor, conventional forms of property crime. Approximately half of all LFFE arrests and two thirds of female LFFE arrests were for shoplifting and writing bad checks. In contrast, less than 5% of all LFFE arrests and less than 3% of female-related arrests involved white-collar occupational crime.

There is research to suggest that a woman's chief motivation for perpetrating property offenses is perceived economic necessity (e.g., to provide for her family) or to earn the validation and approval of a male partner. A man, on the other hand, is more likely to commit property crime to satisfy a need for adventure and/or to elevate his status. Once again, these gender-based goals are consistent with relational-cultural theory, suggesting that

women place ultimate value upon relationships, whereas men prioritize individual achievement.

FEMALE OFFENDERS: PATTERNS AND EXPLANATIONS

Evidence clearly illustrates that girls and women in the United States commit considerably less crime than boys and men, particularly less violent

crime. However, media reports and official crime statistics have suggested that girls and women are catching up to their male counterparts, engaging in more illegal activity than ever, particularly more violent activity. The goal of this entry is to review how (and if) the nature of female offending has changed over time (relative to male offending), describe and evaluate two hypotheses put forth to explain the seemingly narrowing of the gender crime gap—the behavioral change hypothesis and the policy change hypothesis—and lastly, to examine the nature of female-perpetrated crime over the life span of a typical female offender in comparison to a typical male offender.

Trends in Female-Perpetrated Crime Over Time

Trend analysis of official arrest statistics in the United States from the 1980s to the mid-2000s shows that while the Violent Crime Index—a composite measure of homicide, aggravated assault, rape, and robbery—had declined slightly (6%) for adolescent males, it had actually increased by 87% for adolescent females. Although, closer examination of the data shows that aggravated and simple assault were driving this surge—as robberies, rapes, and homicide had stayed constant.

More recent analyses of U.S. arrest statistics from 2005 to 2014 show that the overall crime rate is declining for both genders, irrespective of age, and the decrease is most pronounced among adolescents—boys in particular (51.7% decrease for boys; 38.5% decrease for girls). All forms of serious violent crime—robbery, homicide, and aggravated assault—have also declined substantially and to virtually the same degree for both adolescent males and adolescent females between 2005 and 2014. Conversely, there has been a noticeable *increase* in seemingly economic-motivated crimes (e.g., robbery, burglary, theft/larceny) perpetrated by females, albeit this upward trend is mainly attributable to adult females. In contrast, the same increase is not evident for males.

Despite evidence to the contrary, the perception that females are more dangerous and violent than ever remains. Arguably, this is due to several factors. Highly publicized media cases and YouTube

clips continue to surface detailing stories about girls and women who have killed or seriously hurt ex-lovers, boyfriends, or family members. Stories range from the female high school student who stabbed a male classmate to death because he would not be her prom date to the U.S. gold medalist soccer player Hope Solo who was arrested in 2014 for assaulting her sister and 17-year-old nephew. Moreover, book titles such as *Sugar and Spice and No Longer Nice: How We Can Stop Girls' Violence* send a message that female-perpetrated violence is a modern problem that needs solving.

Consequently, scholars continue to explore whether female-perpetrated violence and illegal activity have genuinely surged over time. Specifically, scholars have developed two hypotheses to help explain the apparent surge in female-perpetrated crime: (1) the *behavioral change hypothesis*—yes, girls and women really have gotten worse, in large part due to the emergence of feminism and (2) the *policy change hypothesis*—no, girls and women have not changed; rather, societal attitudes toward girls and women have changed, which in turn has altered how society treats females. This latter hypothesis suggests that there is now less chivalry and more equality in terms of the application of existing laws and policies (e.g., more recognition that girls and women could be perpetrators of domestic violence), or that shifts in public policies and enforcement practices might disproportionately impact girls and women (e.g., criminalization of less serious forms of violence disproportionately impacts girls and women).

Behavioral Change Hypothesis

The behavioral change hypothesis contends that females actually are engaging in more illegal and antisocial behaviors, especially more violent-related crimes. This hypothesis further suggests that the greater equality afforded to women and girls in U.S. society has catalyzed a number of changes that in turn have contributed to the apparent surge in female-perpetrated crime, particularly violent crime. First, gender equality has simply increased the desire among girls and women to engage in crime in the same way that girls and women not only desire, but also are

expected to, work outside the home. Second, gender equality has also provided more opportunities for girls and women to engage in crime as a consequence of less supervision and more freedom. Third, changing gender norms (catalyzed by social media and movie portrayals of women in violent roles—e.g., the 2003 movie *Kill Bill*) have encouraged females to use physical aggression as a legitimate means of resolving interpersonal conflict or affecting revenge. Fourth, as a result of gender equality, girls and women are increasingly experiencing economic stress; as a consequence, they are turning to alcohol and/or drugs more frequently as a means to self-medicate, which in turn may lead to criminal justice involvement.

Policy Change Hypothesis

Researchers studying crime trends generally agree that policy shifts have lowered the tolerance of law enforcement toward low-level crimes and misdemeanors, which has resulted in more arrests for less serious crimes. The policy change hypothesis suggests that this *net widening* has disproportionately impacted girls and women, given their greater relative participation in less serious categories of offenses that have been the primary casualty of net widening policies. In fact, careful analysis suggests that crimes such as disorderly conduct, harassment, and resisting arrest are now more likely to be categorized as simple assault. Similarly, simple assault is more likely to be upgraded to aggravated assault. Thus, girls and women in particular are disproportionately impacted by these changes, given that when females commit violence, they tend to commit mild and less serious threats or physical attacks. The policy change hypothesis also stipulates that less tolerant family and societal attitudes toward adolescent females have amplified girls' arrests as has the criminalization of violence in private settings and schools—female-perpetrated aggression is more often relational (relative to male-perpetrated violence) occurring within the context of a close relationship.

Evaluating the Behavioral Change and Policy Change Hypotheses

To evaluate the behavioral change and policy change hypotheses as potential explanations of

girls' delinquency, some researchers carefully analyze multiple data sources. For instance, researchers may use official police arrest statistics or other government data such as court convictions. Others draw on unofficial data, using surveys or interviews with offenders or victims. Each source of data has its associated strengths and weaknesses, and often each portrays a slightly different picture of crime. Taken together, however, a reliable story emerges.

Darrell Steffensmeier and colleagues have conducted some of the most systematic research in the area of gender differences and crime. Relying on three sources of data (official government statistics, victimization surveys, and self-report data), Steffensmeier and colleagues' work has indicated that the rise in girls' violence is only evident in the official arrest data; unofficial reports from victims and offender do not corroborate the official statistics. Specifically, in contrast to conclusions about rises in girls' violence based on arrest statistics, results from sources independent of the criminal justice system (i.e., victimization and self-report surveys) show very little overall change in girls' assault levels or in the Violent Crime Index and, most notably, essentially no change in the female-to-male percentage of violent offending. These divergent findings across data sources point to gender-specific effects of policy changes rather than shifts in female-perpetrated aggression.

Life Course Theory and Female Offenders

Since the mid-1970s, a group of researchers known as *developmentalists* or *life-course theorists* have taken a different approach to understanding how crime changes over time. These researchers have assessed and reassess the same group of people at multiple intervals throughout their life span. Sometimes these researchers have been able to study the same group of people from birth well into late adulthood.

These researchers have collectively illustrated that there is a small, albeit core group of chronic offenders who account for the vast majority of crime. These individuals, named *life-course-persistent offenders*, manifest criminal tendencies early in life. In childhood, they tend to show evidence of antisocial problems such as temper tantrums, lying, and theft. In adolescence, many are

involved with substance use or abuse, fights in school, aggression toward peers and teachers, and problems at home such as conflict with parents. Terrie Moffitt, one of the foundational researchers in this field, argues that these early *crime* manifestations are normally accompanied by neurological deficits, which are present at, or soon after, birth. Examples include late verbal development, psychomotor delays, poor impulse control, and attention-deficit disorder. Although Moffitt further suggests that there is often a genetic link, adverse events, poor family functioning, and/or impoverished environments could compound preexisting vulnerabilities, and the cumulative effects of these multiple risk factors lead to failure to thrive in multiple domains—education, employment, and relationships—thus crime ensues.

Importantly, the evidence suggests that males significantly outnumber females in the life-course-persistent category (one estimate places the male-to-female ratio at 10:1). Moffitt has hypothesized that this disparity exists largely because a female is much less likely to possess key risk factors that put a child at risk for developing into a life-course-persistent offender. Namely, girls are significantly less likely to experience neurological deficits, hyperactivity, or developmental delays in verbal and executive functioning.

Moffitt's seminal research has also identified a second category of offender: the *adolescent-limited offender*. Unlike the life-course-persistent offender, the adolescent-limited offender is almost as likely to be male as female. Furthermore, this class of offender does not experience any of the predispositional vulnerabilities that the life-course-persistent offender possesses; they do not exhibit early-onset childhood aggression, neurological deficits, or any inclination toward criminal activity until adolescence. Minor crimes and antisocial behaviors such as experimentation with drugs or alcohol, vandalism, defiance of authority figures, and stealing items of small value characterize the adolescent-limited offender. Not only does Moffitt consider these behaviors normative during adolescence, she also posits that these antisocial tendencies will dissipate as adolescence terminates and adulthood emerges.

Moffitt further asserts that these normative antisocial tendencies coincide with the onset of adolescence due to a maturation gap—teens want the freedoms associated with adulthood (e.g.,

wealth, independence, respect); yet, because they are not quite attainable, an adolescent will mimic the behaviors of the life-course-persistent offender who seemingly has achieved all the freedoms of adulthood. She posits that female and male adolescents equally desire independence; hence large gender differences are not expected in the prevalence of adolescent-limited offenders; however, it is expected that girls will engage in the antisocial behaviors associated with this type of offender group less frequently than males; the hypothesized reason is that the associated risks are higher for females (e.g., pregnancy), and females do not have the same degree of access to life-course-persistent offenders as their male counterparts do.

FEMALE OFFENDERS: PREVALENCE AND STATISTICS

Historically, scholars and correctional policy makers paid little attention to female offenders. However, this changed radically with the publication of Freda Adler's *Sisters in Crime* and Rita Simon's *Women and Crime* in the mid-1970s. Both authors reported that female-perpetrated crime was increasing at a faster pace than male-perpetrated crime. Adler also concluded that females were becoming more violent. At the time, both authors essentially argued that the rise of feminism catalyzed the apparent surge in female criminal conduct. However, the apparent surge and corresponding explanation have since been convincingly debunked.

Subsequent to Adler's and Simon's seminal works, scholars and government agencies slowly began to report both official and unofficial crime data for males and females separately. Furthermore, scholars began to focus on understanding how the context of criminal behavior (e.g., motivations, victim-offender relationships, degree of victim harm) is both similar and different between the sexes. Today, scholars continue to explore whether the modern-day female really is more violent and criminally active than her predecessor.

This entry provides an overview of the prevalence and types of crime that females commit in comparison to their male counterparts. In doing so, the entry highlights that there is a gender gap in crime—males account for most crime—particularly violent as opposed to nonviolent crime. The entry also illustrates additional nuanced differences such as where the gender gap is most evident (e.g., nonfamilial homicide, rape, robbery) and where it is least evident (e.g., shoplifting,

parents killing their own children). These conclusions are based primarily on the synthesis of the following sources of information: (a) official arrest statistics (Uniform Crime Reports) collected annually by the Federal Bureau of Investigations, (b) official arrest information that provides contextual details about crime not captured within the Uniform Crime Reports (National Incident-based Reporting System), (c) unofficial victimization survey results (National Crime Victimization Survey), and (d) a collection of scholarly works that have examined gender differences and similarities in crime either over the developmental life span or specifically within the context of specialized forms of violence (e.g., intimate partner violence, serial homicide). Importantly, the fourth source of information typically augments official crime data with offender and victim self-reports. Each information source has associated strengths and weaknesses; however, the collective evidence provides a rich and reliable understanding of the types of crime that females commit and how female-perpetrated crime is similar as well as different from male-perpetrated crime.

The Gender Gap in Crime

One universal finding has emerged repeatedly in the criminological literature. Males—men, adolescents, and children—engage in more antisocial behaviors and criminal conduct than their female counterparts. This gender gap in crime persists regardless of the period of study, country of origin, research methodology employed, or disciplinary orientation of the researcher. For example, the 2016 official U.S. arrest statistics revealed that approximately one in four arrestees were female. It is important to note, however, that a significant amount of crime is never reported to police and, hence, is not captured in official arrest statistics. Notably, the 2016 National Crime Victimization Survey suggests that most crime is unreported to police (58% of violent crime and 64% of property crimes). Furthermore, certain crimes such as sexual assault and rape are particularly less likely to be reported (23% reported) versus crimes such as motor vehicle thefts (80% reported). Consequently, the importance of augmenting official crime statistics with unofficial data sources (e.g., direct reports from victims or offenders) is

essential to gain a complete understanding of how much and what types of crime females commit relative to their male counterparts. Careful analysis of multiple sources of data has revealed that while the gender gap is particularly pronounced in some areas, it is less pronounced, and even nonexistent, in others.

Where Is the Gender Gap the Widest?

The gender gap in crime is most amplified within the domain of violent crime, particularly serious forms of violence that occur between strangers and/or acquaintances. Although people are less likely to be the victim of violent as opposed to nonviolent crime, when violent crimes do occur, they more often than not are perpetrated by male offenders.

Official arrest statistics illustrate that male offenders account for approximately nine in 10 homicide, robbery, rape, sexual offense (excluding prostitution), and weapon-related arrests. Extensive research conducted by Darrell Steffensmeier and colleagues comparing official and unofficial data sources report similar trends. Researchers who study serial homicide offenders (e.g., Ted Bundy) and mass homicide offenders (e.g., school shooters) repeatedly find that these crimes are typically perpetrated by males, albeit 16% of serial homicide offenders are estimated to be women.

Another influential group of researchers—known as *developmental psychologists* or *developmental criminologists*—have discovered key gender differences in the prevalence of crime using research methods that extend across the life span of the individuals under study. In essence, these developmental or life span researchers study the same sample of children (in some cases right from birth) into adulthood. These researchers are interested in learning how crime changes (or stays the same) over time within individuals. This body of knowledge has revealed that males, not females, are most likely to be classified as chronic offenders (also known as *life-course-persistent offenders*). Life-course-persistent offenders start engaging in serious forms of antisocial behavior early in childhood (e.g., steal from parents, aggressive toward other children, violent in school) and persist in severity and versatility well into adulthood. Some

scholars estimate that nine in 10 life-course-persistent offenders are male.

Where Is the Gender Gap the Narrowest?

The gender gap in crime narrows considerably in two circumstances. First, as the severity of crime decreases, so does the gender gap; this is particularly pronounced for nonviolent crimes. Second, although males account for nine in 10 homicide arrests, females account for a substantial share of familial homicides (about one third), particularly when the victim is a child or spouse of the perpetrator.

Approximately 40% of criminal incidents include crimes that fall into the category labeled LFFE. LFFE captures the following crimes: larceny (e.g., purse snatching, shoplifting, theft of motor vehicle parts), fraud (e.g., credit card fraud, welfare benefit fraud), forgery (e.g., writing bad checks), and embezzlement (e.g., stealing money or consumer goods from place of employment, stealing money from bank/savings company where one works). Within this LFFE category, the gender gap is particularly narrow. The 2016 arrest statistics illustrate that females account for anywhere between one in three and one in two of these crimes (larceny arrests: 43.5% female, forgery arrests: 36.1% female, fraud arrests: 37.2% female, and embezzlement arrests: 53.1% female).

In 2015, Steffensmeier and colleagues published an in-depth examination of the nature of LFFE offenses by gender using multiple sources of data. These researchers made three pivotal discoveries. First, for males and females alike, the vast majority of LFFE offenses occur in nonoccupational settings (up to 98% and 97% for males and females, respectively). Second, roughly half of all LFFE offenses include mundane crimes such as shoplifting or writing bad checks that involve meager sums of stolen property (median value < \$60.00). Third, there are nuanced gender differences within specific LFFE offense categories: For example, females account for 45% of arrests involving shoplifting, 54.1% of arrests for writing bad checks, and 75% of arrests for welfare fraud. In contrast, males account for the vast majority of arrests involving transportation fraud (jumping subway turn styles, 88% of arrestees are male), stealing contents from motor vehicles (89% of

arrests are male), stripping motor vehicles (90% of arrestees are male), or selling counterfeit street goods (94% of arrestees are male).

A collection of research studies using diverse methodologies has revealed that the gender gap in crime is virtually nonexistent for behaviors that the general public would not necessarily deem criminal. For instance, equal numbers of men and women experiment with marijuana or take prescription drugs for which they have not been prescribed. Similarly, using rich and reliable life span data, developmental researcher Terrie Moffitt has demonstrated that males and females are evenly represented in the commission of trivial forms of delinquency during adolescence (e.g., drinking under age, vandalism, skipping school, experimenting with drugs, shoplifting, cheating, stealing small sums of money). Lastly, 2016 U.S. arrest statistics revealed that females accounted for 50.8% of all prostitution-related arrests. Thus, while predatory sex crimes such as rape are the purview of men, sex work is the purview of women.

As stated, male offenders account for the vast majority of serious violent crimes such as homicide, rape, forcible confinement, and aggravated assault resulting in serious bodily harm. However, a closer examination of violent crimes has also revealed that female offenders account for approximately 28% of (nonsexual) assault-related arrests. Qualitative research suggests that female-perpetrated assaults are motivated by a myriad of reasons including intense emotions (anger, revenge, and jealousy), perceived slights and injustices, self-defense, and within the context of instrumental robberies. In addition, estimates for female-perpetrated spousal homicide have ranged from 20% to 40%.

Considerable research has also been conducted in the realm of filicide—when parents (step or biological) kill their children. This body of literature indicates that mothers and fathers account for close to equal proportions of filicides. However, there appears to be an inverse relationship between victim age and whether the father or mother perpetrated the homicide. Specifically, as the age of the victim decreases, the likelihood that the mother perpetrated the filicide increases. For example, mothers perpetrate the majority of filicides involving newborn. Conversely, as the age of

the victim increases, the likelihood that the father perpetrated the filicide increases. For example, fathers perpetrate close to 80% of filicides that involve adult children.

FEMALE SEXUAL OFFENDERS

Traditional sociocultural views of gender roles have helped prevent the recognition that women also commit sexual offenses. Further, people tend to have difficulties understanding how a woman can sexually offend—the idea being that sexual offending necessarily involves a penis. As a result, female sexual offending has traditionally been minimized and considered nonserious. This entry reviews the nature of sexual offending by women, including its prevalence and the various types of female sexual offenders.

The Nature of Sexual Offending by Women

Female sexual offenders, like their male counterparts, engage in a variety of sexually offending behaviors against male and female victims. Although their victims may be of any age, women predominantly sexually offend against underage victims (children or adolescents). Their sexually offending acts include exposing one's genitals, fondling, oral contact, vaginal or anal penetration, and the use of objects, all of which can be perpetrated on the victim or by the victim on the offender. In contrast to men, women

proportionally engage in less attempted or completed penetration (penile, digital, oral, or with objects) of the victim.

Women, like men, also use electronic means to produce child sexual abuse images (often described as child pornography). The production of these images appears driven by the need or wish to please someone else, typically a man, or for financial gains. For example, besides posting and/or sending photos of their own children at someone's request, women have also engaged in live sexual offending against children, broadcasted via webcams, in a way that suggests they are acting for the pleasure of the viewer in exchange for money. Although the prevalence of women producers of child abuse images is unknown, the evidence suggests that only a very small proportion of women are actual consumers of such images.

Who Are the Victims?

The data show that about one third of female sexual offenders co-offend with another person, most frequently a man who is her spouse. The other two thirds engage in solo offending. When women co-offend with a male partner, the victims tend to be their own children (biological or stepchildren) or children under the care of the woman or couple, such as childcare activity. Of course, male–female co-offenders also offend against adults or against unknown children, but they tend to be in the minority. In contrast to female co-offenders, solo female offenders appear to more frequently sexually offend against nonrelated victims than against related victims. Female sexual co-offenders tend to assault girls, but solo offenders tend to assault boys. It is likely though that the preferential victimization of girls by female co-offenders actually reflects their spouses' rather than their own preference. Finally, evidence suggests that women who co-offend with other women may be those who assault peerage victims, particularly same-sex victims.

Is It All Sexual Offending?

Sometimes, women who fail to intervene in cases of child sexual abuse or who knowingly and/or purposefully allow someone else access to a child for sexual purposes are classified as sexual

offenders. The former refers to women who do not intervene in cases of child sexual abuse that typically occurs within the home. For example, a woman may choose to pretend the abuse is not occurring in order to maintain the relationship with her male partner. The latter refers to women who, for financial reasons, essentially force the child or teenager into prostitution. These women may sell their own children or abuse them on live webcams in return for goods, favors, or money. Alternatively, they may be part of prostitution rings where underage girls are considered a valued commodity.

It is unclear why some women choose to ignore the sexual abuse of children in their homes. It is suspected that the failure to intervene is due to issues such as feelings of powerlessness on the part of the woman, the need to maintain the relationship at all cost, or simply indifference to the child's suffering (perhaps because she had been victimized herself). Research is needed to clarify those issues.

In contrast, research has shown that women convicted of providing sexual access to youth for financial gains (i.e., prostitution-related offenses) are different from traditional female sexual offenders. Women convicted of providing sexual access to a child have histories more consistent with general criminality and exhibit more general antisocial features than women convicted of contact sexual offenses. These findings suggest that these women, in a manner similar to women who sell but do not use drugs, may view sex as a commodity to be exploited for financial gains.

Prevalence

A number of studies have attempted to establish the prevalence of sexual offending by women. Most of these have examined clinical samples of victims or offenders and found widely differing prevalence statistics of the proportion of sexual offenders who are female, ranging from 5% to 50%. Methodological differences, such as the data collection method, definition of sexual abuse utilized, and target populations explain these disparities. Hence, although these statistics speak of the prevalence of sexual victimization at the hand of a woman in specific samples, they do not provide information regarding the overall prevalence of sexual offending by women.

A better estimate of the proportion of sexual offenders who are female is obtained when official data are compared to victimization data. Based on multicountries information, official police or court reports data reveal that approximately 2% of all sexual offenders reported to the police are women. In contrast, an examination of data obtained from self-reported population-wide victimization surveys reveals that the proportion of sexual offenders who are women is 11%, almost 6 times higher than the official rates. These data show that, although there is no way to truly know the extent of sexual offending by women (just as there is no way to know the true extent of sexual offending by men), population-based anonymous victimization surveys continue to be the best tool to estimate the prevalence of both female- and male-perpetrated sexual abuse.

Types of Female Sexual Offenders

Researchers have attempted to establish typologies to better understand the causes and processes of sexual offending among female offenders. Some of these typologies are based on clinical descriptions of cases. Others have utilized more systematic empirical methods to develop their classifications of female sexual offenders.

Typology Based on Qualitative or Clinical Data

The first typology of female sexual offenders identified three types: the teacher-lover, the predisposed, and the male-coerced. These types were based on the offenders' characteristics and their motivations for the sexual offenses. The *teacher-lover* sexual offender is an adult woman who acts as the initiator of the sexual abuse of an adolescent, usually a male. The offender tends to be in a position of power through her age and her role in the victim's life, for example, as a teacher (hence the title). Within this context, this woman considers the adolescent her equal who desires the sexual relationship and benefits from her sexual favors.

The second category, the *predisposed* sexual offender, also acts alone. These women tend to have a long history of varied and severe childhood sexual victimization starting at a very young age (i.e., under 6 years of age) but believe that, somehow, they were responsible for it. During

adolescence, they tend to turn to substance use (e.g., food, alcohol, drugs) as a way to cope with the impact of their victimization. For the most part, the victims of predisposed offenders tend to be family members, often their own children. The sexual offenses tend to involve physical as well as sexual violence.

The third and final category is the *male-coerced* sexual offender who engages in sexual aggression in the company of a male. This type of offender tends to hold traditional views of gender roles, with the man being in a dominant position. These women are characterized by negative relationships with, and fear of, men while concurrently believing they need a man to care for and protect them. As a result, they engage in marital relationships with men who dominate them and subject them to emotional, physical, and sexual abuse. Despite this abuse, because of their fear of being alone, these women feel they need to preserve the relationship at all costs. They are typically reluctant to participate in abuse but do so because of emotional dependence, fear of abandonment, or fear of punishment. It is important to note that this category of male-coerced offenders has been debated in the literature. Generally, findings show that not all women who offend in company of their boyfriend or spouse have been coerced. Some women willingly participate and some even initiate the abuse.

Typology Based on Quantitative Data

Typologies based on statistical analysis examine criminological variables such as the total number of arrests, the relationship between the offender and the victim, the type of sexual offense, the ages of the offender and the victim, the victim's gender, drug use, recidivism, and violations of supervision history. They yield a broad range of types of female sexual offenders, only some of whom resemble the types described above, such as *heterosexual nurturers* (akin to the teacher-lover type), *noncriminal homosexual offenders* (with young adolescent female victims), and *young adult child exploiters* (youngest group at arrest with a mean age of 28 years, and youngest group of victims with a mean age of 7 years). Other types include *homosexual criminals* (whose behavior appeared based on economic rather than sexual reasons) and *aggressive homosexual offenders*

(most likely to be convicted of sexual assault against adult females). Other categories consist essentially of variations in the difference between the offenders' and their victims' ages, and the gender of the victim, indicating that typological descriptions of female sexual offenders are sample dependent.

Limitations of Typologies of Female Sexual Offenders

Typologies are meant to provide useful systems to permit a better understanding of the functioning and behaviors of female sexual offenders. To be helpful, however, typologies must be associated with a theory to explain sexual offending by women. Typologies based on clinical data provide psychologically based information that contributes to the development of such theory. Because of small sample sizes that do not account for the full range of female sexual offenders, theoretical developments are limited. Typologies based on statistical analyses of criminological variables provide a better classification of types of female sexual offenders but fail to account for the presence of a co-offender, an important variable linked to female sexual offending, and do not include information on the psychological functioning of these offenders. As such, their usefulness for theoretical development is also limited.

Toward a New Classification of Female Sexual Offenders

Among men, the gender of the victim indicates a particular sexual preference that helps understand the sexual offending behavior. Among women, gender of the victim does not appear to contribute to play a particular role in the sexually offending behavior. Instead, a better classification appears to be one based on age of victims. The convergence of data indicates that one group of female sexual offenders appears to focus strictly on adolescents (mostly males), while another appears to exclusively offend against children. The third category, albeit little studied because of the paucity of data, is comprised of women who assault adults, often other women. Within each of these categories, women may commit their offenses by themselves (solo offenders) or engage in sexually offending

behavior in company of others. Categorizing female sexual offenders according to their preferred victim age in interaction with the presence or absence of a co-offender might provide more useful information on the criminological and psychological characteristics of various categories of female sexual offenders. Of course, this hypothesis awaits empirical verification.

FEMALE SEXUAL OFFENDERS: PATTERNS AND EXPLANATIONS

Female sexual offenders are a diverse group of individuals with differing motivational and offending patterns. Evidence indicates that female sexual offenders, like male sexual offenders, have problematic issues in the four broad areas related to sexually offending behavior, namely, the cognitive, emotional, relational, and sexual domains. Despite these similarities, the ways in which problems manifest themselves in these various domains differ according to the gender of the offender, indicating that gender-informed explanations of female sexual offending are required. This entry reviews the offense patterns of female sexual

offenders, the explanatory factors related to sexual offending that are specific to women, and their risk of recidivism.

Female-Specific Offense Process

There have been a number of attempts at establishing the offense process of female sexual offenders based on patterns of contextual, behavioral, cognitive, and affective events that facilitate and maintain female sexual offending. These studies show that female sexual offending, like male sexual offending, takes place within the context of a negative life pattern, which consists of negative styles of thinking, unhealthy emotional and sexual regulation, and unproductive or counterproductive coping strategies that eventually lead to the sexually offending behavior.

Female sexual offenders' personal histories and life circumstances are remarkably similar across studies. These women have problematic personal histories that consist of relationship problems; victimization histories and associated mental health problems; and major life stressors related to work or financial difficulties, health problems, and legal difficulties. These factors set the stage for problems with substance abuse, poor boundaries in the child–adult relationship, and adopting a passive approach to life. Various combinations of these elements set up the conditions for three different gender-specific pathways to offending.

One pathway, called *directed* or *co-offending*, describes women who co-offend with their male partners. Co-offending processes involve abuse by the partner, wishing to please the partner, giving in to demands, social isolation of the woman, or using the children as bargaining chips for personal or financial gains. Research also shows that offending couples tend to have particularly unconventional sexual lives that include activities such as frequenting swingers' clubs, sexual relations with strangers or with the spouse's friends, or sexual relations in public places. Pornography is also frequently viewed, often in the presence of the children. In this pathway, the sexual offending behavior is not an isolated incident; it tends to repeat itself over numerous occasions, sometimes over long periods of time.

As such, women who co-offend with their male partners play rather different roles at different

times over the series assaults. A woman can be at times *passive*, which means she observes, facilitates, or is indifferent when an act of sexual abuse is happening. For example, she may encourage the child to go see the co-offender or convince the child to participate in the sexual act. At other times, she may be *directed* into the offending behavior, meaning that she follows the lead and instructions of her male co-offender on a particular occasion. Being directed does not mean that the woman is being coerced; it simply means that she is not taking the lead during the commission of a given offense. Finally, the woman may choose an *active* involvement, entailing that she makes her own sexual behavior choices during the assaults. Research shows that women who initially sexually offend because of coercion from their co-offenders tend to be passive or directed during the offenses. In contrast, noncoerced women tend to be directed or active.

The second pathway, called *implicit-disorganized* or *solo*, refers to an offense process that involves women establishing a relationship with the victim in efforts to meet their own interpersonal and emotional needs. Within this context, victims tend to be viewed as adultlike and as having engaged in a consensual and reciprocal relationship. In this pathway, the woman adjusts circumstances to increase the physical and emotional contact with the victim. For example, she may establish a pattern of adultlike relational behaviors with a young victim, such as discussing intimate sexual details of her life. As the opportunity increases, the woman will often impulsively take advantage of a situation to fulfill her immediate needs, such as sexual or intimacy desires, but does so in an unorganized manner. Alcohol is frequently present in this offending process, and co-offending tends to be absent. Although victims can be of any age, they tend to be older youths or adults.

The third pathway, called *explicit approach*, describes a process in which women explicitly planned their sexual offenses with specific goals in mind, such as sexual gratification, intimacy with victim, revenge and humiliation, or financial reward. The latter goals refer to those women who sexually exploit a youth for financial gains, such as those found in prostitution-related offending. The women in this pathway tend to

experience positive affect, such as excitement or satisfaction, in relation to their offenses and exhibit cognitions congruent with those emotional states, such as thoughts of revenge or anticipated financial gains. Both solo and co-offending are found in this pathway although in cases of co-offending, the women always offend under their own volition. Alcohol is not typically involved, and victims may be of any age, although they tend to be female. Generally, the women in this pathway tend to demonstrate the most antisocial features, such as a history of nonsexual offending and attitudes supportive of criminal activity.

Gender-Specific Factors Related to Sexual Offending Among Women

Female sexual offenders are a diverse group of individuals with differing motivational and offending patterns. Although these women, like their male counterparts, have problematic issues in the four broad areas related to sexually offending behavior (namely, the cognitive, emotional, relational, and sexual domains), the ways in which problems manifest themselves in these various domains differ according to the gender of the offender. Hence, to understand female sexual offending, gender-specific issues must be taken into consideration.

Offense-Supportive Cognitions

Unsurprisingly, women, like men, minimize and justify their sexually offending behavior. The underlying motivations for this denial and minimization are likely to be highly similar to those of males, such as shame or wanting to share responsibility with others. There is evidence, however, that once females acknowledge they have engaged in sexually offending behavior, their minimizations and rationalizations also disappear. There are also suggestions that the patterns of denial and minimization of women with a co-offender are different from those who only engage in solo offending. Some women with co-offenders may wrongly take responsibility for the offending behavior of their partners, while others squarely blame their partner for the offending behavior or continue in an entrenched denial of the offenses if they are still romantically involved with their partners.

In terms of general offense-supportive cognitions, research indicates that female offenders, like males, believe that males are specifically entitled to sexually offend. In contrast to male sexual offenders though, they do not tend to view themselves as sexually entitled nor do they view all children as sexual beings. They do view their own victims as being interested in sex and, interestingly, tend to view men as dangerous. This evidence suggests female sexual offenders possess some gender-specific cognitive patterns that have been influenced by their own histories as well as societal messages about gender roles.

Relationship Issues

Problematic relationships appear to be particularly relevant for female sexual offenders. Among male sexual offenders, problems in relationships tend to manifest themselves through some form of emotional identification with children, instability in current intimate relationships, hostility toward women, general social rejection/loneliness, and a general lack of concern for others. In contrast, female sexual offenders tend to exhibit a pattern of relationships characterized by abuse and a lack of practical and emotional support from family and friends. The presence of a prior or current violent partner, a history of having been physically or sexually victimized, being socially isolated, and having unhealthy emotional dependence on others are also common features of female sexual offenders.

Women tend to form their self-identity and sense of self-worth in relation to important others (e.g., family, friends, and romantic partners). Strong social bonds and attachment to family, partner, and friends are all important components of women's well-being. The findings that female sexual offenders exhibit problematic relationship histories replete with various forms of victimization suggest that attachment issues, although important for all sexual offenders, may play a particular role in women's sexual offending. Attachment problems resulting from past abusive relationships may lead a woman to seek sexual closeness with a nonthreatening partner, such as a child, to meet her emotional needs for closeness and sense of affiliation. For other women, the same needs for affiliation, coupled with a

tendency to gravitate toward unhealthy partners due to past experiences, may cause them to eventually acquiesce to deviant sexual behaviors, including sexual abuse, in order to preserve the relationship.

Sexual Issues

Some female sexual offenders report deviant sexual fantasies and arousal related to their offenses, suggesting that the presence of pedophilic sexual arousal and fantasies might provide an important motivating factor for the sexually offending behavior. For some of these women, however, this pedophilic interest appears related to their own histories of sexual victimization as a child, suggesting that the nature of female sexual paraphilic preferences may be different than that of male sexual offenders.

Research into nonoffending men and women demonstrates that, although men's physiological sexual arousal actually reflects their sexual preferences, women's arousal patterns are much more fluid and tend not to demonstrate such specificity. These results suggest that sexual arousal patterns, like many factors related to offending among female sexual offenders, are gender-specific rather than gender-neutral. Specifically, it appears that the traditional model of sexual activity cycle that consists of desire, arousal, orgasm, and resolution does not apply to most women, except in the beginning stages of a relationship. In contrast to males' erections, women's genital arousal produces little conscious feedback. Consequently, women evaluate their subjective sexual arousal by appraising the whole situation, which includes the potential of rewards, such as the possibility for emotional and/or physical closeness, a sense of commitment, love, and acceptance by their partner. When the woman senses the presence of these potential rewards, she will deliberately engage in sexual activity, her choice being based on needs other than a desire for sexual release. As her other needs are being met, the sexual contact leads to an increased sexual desire and arousal. There is some evidence that for some female sexual offenders, this pattern of arousal is related to their offending behavior. Many women engage in sexual coercion to fulfill a need to achieve an interpersonal connection.

Risk of Sexual Recidivism

Research shows that female sexual offenders' base rates of recidivism are significantly lower than that of males. Meta-analytical findings for 2,490 convicted female sexual offenders show that about 20% of female sexual offenders recidivate with a new crime of any type after being convicted for a sexual offense, but that only 6% commit a new violent (including sexual) offense. When only new sexual offenses are examined, the studies show that only 1.5% of female sexual offenders commit a new subsequent sexual offense. These findings show that once a woman has been detected and sanctioned for a sexual crime, she is not likely to commit a new one, indicating that patterns of sexual recidivism, like patterns of sexual offending, are gender-specific.

FEMALE VIOLENT OFFENDING, THEORETICAL MODELS OF

Women comprise a small population of adults arrested and sentenced for violent offenses within the United States—14% and 5%, respectively, in 2015 according to the national statistics from the Bureau of Justice Statistics. Common categories of violent crime are robbery, assault, and homicide. Analyses of national data available through the Bureau of Justice Statistics show that rates of violent crime by women have been relatively stable since the mid-1960s. Despite some isolated increases in rates of assaults, rates of other violent offenses by women have dropped since 1990. The increase in the number of women arrested for assaults is often attributed to the implementation of mandatory arrest policies for domestic violence incidents.

Women convicted of violent offenses are more likely to have histories of certain adverse childhood experiences, such as abuse, single-parent household, and parent with mental health concerns, than women convicted of nonviolent offenses. Additional research suggests that women with violent offenses engage in more severe substance use (e.g., younger starting age and higher rates of polysubstance use) and have higher rates of mental health disorder symptoms than women without violent offenses. However, no one factor significantly distinguishes women convicted of violent offenses from women convicted of nonviolent offenses.

Women's violence is connected to the context of their primary relationships. Women convicted of violent offenses describe being introduced to criminal activity, criminal networks, and violent crime by their male partners. Over three fourths of violent women offenders commit their offenses with co-offenders, and fewer than 14% of women have a primary role in the offense. Research analyzing the role of these male co-offenders indicates that women frequently are 1-time violent offenders. Only a small proportion of women engage in repeat violent offending.

Women's acts of violence are mainly isolated events that occur within the context of an established relationship. Nearly half of all homicides

perpetrated by women involve an intimate partner with an additional one third of victims described as acquaintances. Nationally, 15% of women have reported physically striking a partner, 8% a friend, and 6% a stranger. The most commonly reported motivation for women's use of violence with intimate partners is self-defense. Women who are violent against their intimate partners have low rates of general violence (e.g., street fights). Given the relational aspect of women's violence, most research focuses on women's engagement in intimate partner violence with limited attention to general violence (i.e., violence perpetrated against targets other than partners, such as community members and strangers).

A few differences exist between women's acts of general violence and intimate partner violence. Women have described their experiences of general violence perpetration as more likely to have a female victim, occur in public space with involved bystanders, and motivated by feeling disrespected by another woman, whereas women's descriptions of experiences of intimate partner violence perpetration more often have a male victim and occur in private spaces. Both groups of women frequently report extensive trauma histories; however, women who engage in general violence have higher rates of trauma-related symptoms and histories of witnessing maternal violence. Only a limited body of research examines women's engagement in a range of violent behaviors.

Theories explicitly investigating women's involvement in criminal behaviors have evolved over time, and this entry focuses on these theoretical shifts.

Traditional Models of Violent Offending

The majority of theories about female offenders have focused on issues surrounding women's increased involvement in crime over time, with scant attention to violent crimes committed by women. Theories that have explored women and violence typically have tried to explain why women are less likely to commit violent crimes than men. Early on, these theories centered on biological differences between men and women and included references to testosterone, neurochemicals linked to impulsivity, and the greater muscular strength of men. Later, cultural and

socialization theories dominated the literature on gender differences and violence. Pivotal to these theories is the differential socialization of men and women; men are more commonly rewarded for violence, and women are taught to suppress aggressive impulses. As an extension of socialization theories, liberation theory suggests that socialization processes have changed over time due to the second wave of feminism and women's emergence into nontraditional sex roles. As a result, women have supposedly adopted more masculine behaviors, including violent behaviors. However, these theories have not been extensively tested or backed up with empirical investigation.

Theoretical Shifts for Women and Violence

Apart from the theories that address the gender disparity in violent crime rates, the question of why some women commit violent crimes and others do not has been largely neglected. The theories that have emerged incorporate many of the risk factors for violent offending that are relatively unique to female populations. This has resulted in a shift away from the mere extension of male-centered theories of violent crime that was characteristic of much of the early correctional literature; many theories such as social learning theory and differential association theory were based on research with samples of only men and with little attention to gender. Theories that portrayed women who commit violent acts as social deviants with biological aberrations have largely been discredited. Current theorists underscore the importance of context, considering the role of social, structural, political, and economic factors. Two theoretical approaches, pathways theory and trauma theory, provide insight into factors associated with women's violence, and in addition, two other theories seek to explain why some women are violent and some are not: the Feminist Ecological Model (FEM) and the overcontrolled-undercontrolled personality concept.

Pathways Theory and Trauma Theory

Differences in life experiences between men and women offenders have supported pathways theory, a theoretical perspective on women's trajectories into criminal activity, including violent

behaviors. Pathways theory focuses on how women's lives are influenced by structural oppression, gender expectations and gender socialization, and punitive societal responses to certain behaviors. In addition, trauma theory posits that experiencing trauma can distort women's conceptualizations of healthy relationships and hamper psychological development. Women's experiences of trauma and adversity (e.g., childhood abuse and neglect, parental substance abuse, housing instability) are linked to women's involvement in violence. Biological and psychological studies of the effects of trauma demonstrate links between traumatic experiences, women's processing of events, relational patterns, responses to additional life stressors, vulnerabilities to substance use, and ultimately, engaging in violence.

Women involved in the criminal justice system report extensive histories of childhood adversity and trauma at higher rates than men involved in the system. Childhood adversity and trauma have been linked to adult risk factors (e.g., substance use disorders) and involvement in violent behavior for women. Also, women with histories of childhood adversity and trauma have higher rates of arrests and convictions for violent crimes than women without such histories. Furthermore, childhood adversity and trauma are specific significant risk factors for women's perpetration of intimate partner violence.

Victimization is often prevalent across the life course for women offenders. For example, childhood victimization is a significant risk factor for adult victimization, which is linked to general violence and intimate partner violence perpetration by women. The theme of the research about violent women offenders is that they are often simultaneously victims and perpetrators of violence, especially with their male partners. Women who experience both roles also more often have high rates of childhood adversity, neglect, and abuse.

Pathways and trauma theories provide insight into the disproportionate factors that women offenders experience with an understanding of the connections between life events. Pathways theory positions these factors within a larger societal context and considers the particular intersections of life factors for women. These theories provide some insight into the factors connected to women's involvement in violence.

FEM

The FEM stresses the context in women's commission of violent acts. This model addresses the complexity of women's violence, taking into account interactions between social, historical, institutional, and individual factors, and has been recommended for understanding women's violence. The model consists of four interactive levels, with the first situating the individual in the environment. At this level, several factors are prominent: cognitions, temperament, socialization, interactions with significant others and dimensions of identity (e.g., ethnicity, class, age). The second level, referred to as the *microsystem*, is concerned with the family environment and the important role it plays in shaping the individual's thoughts and beliefs. The FEM suggests that gender and culture influence how individuals interact with their families and immediate environments. The next level, the *exosystem*, is the broader community outside the home, including the individual's school and neighborhood. The final level is the *macrosystem* or society at large. It includes factors such as culture, socioeconomic group, media influences, and exposure to violence. Each of these systems or levels interacts with the others in a reciprocal fashion, thereby shaping individuals' lives and developmental processes. This model guides research on women's use of violence, and positing violence is influenced by exposure to violence within the family, community, and larger culture.

Although few studies apply FEM to violence perpetrated by women, variables associated with each of these levels have been identified as risk factors for violence among women. For example, histories of family violence, negative peer influences, and exposure to violent media images are prominent factors among women with violent offenses. Women's exposure to risk factors across levels and the life course may increase the likelihood of women's violence.

Overcontrolled and Undercontrolled Personalities

Theories that examine overcontrolled and undercontrolled personalities emphasize that factors both internal and external to the individual are instrumental in predicting violence.

Theorists initially identified these personality styles among male juvenile offenders and found the undercontrolled personality to be particularly characteristic of aggressive boys. Lowered inhibitions against aggressive behavior lead to the likelihood of aggressive responses when frustrated or provoked. Overcontrolled aggressors are far less common but tend to be young men who commit extremely violent crimes, such as homicide. These offenders show lower overall rates of aggression. It is hypothesized that these men inhibit their feelings of anger, which results in anger accumulating over time and through repeated provocation, with the ultimate result being an isolated explosion of anger and violence. In 2000, researchers analyzed the overcontrolled hostility construct with a sample of women offenders. The hostility construct effectively identified the 1-time offenders from the repeat violent offenders and nonviolent offenders. In contrast, repeat violent offenders showed undercontrolled attributes. This empirical application of the overcontrolled personality concept provides significant clinical implications for working with violent women offenders.

Treatment Directions

Across research, several factors are key target areas for treatment programming and services for women convicted of violent offenses. These factors include adverse childhood experiences, adulthood victimization experiences, relational dynamics and relationships across the life span, substance use, mental health, and anger. Research reviews of programming available for women involved in the criminal justice system have found that a majority of treatment opportunities for women focus on reducing substance use; however, developments in gender-responsive and trauma-informed programming include a broader array of issues and outcomes for women. As a hallmark program, one intervention was created specifically for women convicted of violent offenses, titled *Beyond Violence: A Prevention Program for Criminal Justice-Involved Women*. This program incorporates multiple theories with a focus on women's anger, mental health, substance use, relationships, violence victimization and perpetration, and community experiences. Positive short-term and long-term outcomes for this intervention have been found across studies with multiple

populations and in different state prisons. Overall, more research is needed regarding efficacious treatment options regarding women and violence.

FEMINIST PERSPECTIVES ON CRIME

Feminist perspectives on crime consider gender and gender inequality as central components necessary to fully understand patterns of criminal

offending, victimization, and interactions with the criminal justice system. A gendered analysis of crime is fundamental to a feminist perspective to understand what behaviors are defined as criminal, why and how women's criminal behavior is different or similar to that of men, and how society responds to men and women who commit actions deemed as crimes. This entry focuses on the key elements of feminist perspectives on crime, beginning with describing patterns of criminal offending and victimization, key concepts that comprise a feminist perspective, and a general and historical overview of the development of feminist perspectives on crime.

Gender Differences in Patterns of Criminal Offending and Victimization

Data on patterns of criminal victimization and offending in the United States provided by the Bureau of Justice Statistics and the Federal Bureau of Investigation demonstrate important gender differences. All evidence indicates that not only are men arrested for crimes at a different rate than women, the crimes they are arrested for are not the same as those for which women are arrested. Arrest data show that more men than women are arrested for committing crimes, and the majority of prisoners in state or federal prisons are men.

Patterns of criminal offending and victimization also vary by gender. For example, men are more likely than women to be arrested for violent crimes, whereas women are more likely than men to be arrested for prostitution. In addition, there are important gender differences in types of victimization experienced. For example, women are much more likely to experience sexual victimization than men, whereas men are more likely than women to be victims of homicide. The relationship between the victim and the offender also varies by gender and highlights the different risks faced by women compared to men. One clear difference in victimization risk occurs for homicide. Although there are fewer female than male victims of homicide, women are more likely than men to be killed by their intimate partner, and men are more likely than women to be killed by a stranger.

Overall patterns of offending have changed over time. Official crime rates, as reported by

government entities like the Federal Bureau of Investigation, have decreased just as new behaviors, such as identity theft, have been identified as crimes. For some offenses, the gender gap has decreased. Clearly, crime does not impact men and women in the same way, but what accounts for these patterns and different levels of risk? Although the gendered patterns of crime have not historically been the focus of mainstream criminology, scholars studying patterns of victimization and offending from a feminist perspective consider gender as a key component to explaining these patterns.

Gender and Oppression as a Key Component of Feminist Perspectives on Crime

Feminist perspectives on crime are characterized by a central focus on gender as a social construct. Different from biological sex, gender encompasses socially defined expectations and characteristics of femininity or masculinity, gender identity, and gender expression. Because it is socially, rather than biologically, constructed, gender is fluid and varies across and within cultures and changes over time.

Sex is biological and sex differences include differences in reproductive organs and hormones that affect physical size and stature. In contrast, gender differences occur as a result of societal expectations for men and women. For example, women, unlike men, are generally born with reproductive organs that make it possible for them to bear children; this is a sex difference. Expectations that women, not men, leave the paid workforce to care for children are gendered.

The distinction between sex and gender has important implications for understanding crime. The relationship between individuals and social institutions is complex, with no single factor explaining behavior. Similarly, there is no single feminist theory. Feminist perspectives do, however, share a common understanding or framework that social institutions are shaped by gender and hierarchically ordered with men in a dominant position over women. Feminist perspectives on crime therefore consider how this unequal relationship, based on gender, frames definitions and explanations of criminal behaviors. Feminist criminologists argue

that to significantly and positively impact the understanding of crime and criminals, including women and other marginalized groups, is not only important but essential.

General Overview of Feminist Perspectives on Crime

Feminist perspectives on crime consider that the history of criminological theory and research has been dominated by a masculine perspective that has influenced the types of questions asked by scholars, the data collection methods, and the interpretation of research findings. As the field of criminology was established, men comprised the majority of scholars studying crime. Their focus was on those individuals who made up the majority of criminal offenders (i.e., men). Furthermore, these scholars were predominately White and economically privileged. Thus, the lens through which they examined criminal behavior was shaped by their own background and experiences. Feminist scholars challenged this viewpoint as they looked for new ways to include the voices of women in research and policy discussions about crime and criminal justice. They argued that the experiences of women were not the same as those of men and that the full picture of crime was impossible without considering how gender, gender inequality, and crime were interconnected. By excluding the experiences of women as victims and offenders, they argued, criminologists had developed an incomplete picture that hindered their understanding of crime. To clarify, feminist scholars were not advocating for criminologists to study women at the exclusion of men. Rather, they were arguing the importance of considering the perspectives of women offenders and victims that had not previously been included.

The feminist perspective also includes thinking about the methods used to collect the necessary data to understand crime. Feminist methodologies focus on giving voice to the individuals who are part of the research rather than speaking for them. Often, feminist methodologies are associated with qualitative research methods. For example, in-depth interviews of female offenders where they talk about their experiences leading up to and including their criminal offenses provide important insight and meaning that would not be obtained if only demographic characteristics were

considered. However, feminist scholars also use quantitative methods. With a better understanding of the unique experiences of men and women, for example, researchers can develop more accurate qualitative and quantitative methods of collecting data on sensitive subjects such as rape and intimate partner violence. It is not the specific method, *per se*, but the approach of identifying the most appropriate method to convey the experiences of those studied that is important. Furthermore, a critical analysis of the research process itself and an understanding of the relationship between the researcher and the research participants are integral parts of feminist methods.

Although there is no singular feminist perspective, and the multiple perspectives encompassed under the umbrella of feminism approach gender inequality from different viewpoints, they share a common focus on explaining women's oppression. Feminist criminology examines crime and victimization within the framework. Historically, five main types of feminist perspectives and their key components are commonly discussed: liberal, radical, Marxist, socialist, and postmodern feminism.

Liberal feminism attributes the oppression of women to differences in how men and women are socialized. Gender differences in crime occur because these differences provide fewer opportunities for women to offend. By comparison, radical feminism views patriarchy as the central component to the oppression of women. Radical feminists focus on crimes against women such as sexual assault as expressions of a patriarchal society.

A Marxist feminist approach argues that women's oppression is a result of inequalities inherent in a capitalist system. Capitalist societies have a gendered division of labor that promotes violence. Socialist feminism builds on both Marxist and radical feminism and argues that the intersection of inequalities based on both sex and class serves to oppress women and that crime occurs within this context.

Postmodern feminists argue that to understand crime it is necessary to understand the uniqueness of each individual woman's experiences as they are shaped by their position in the social structure. It is not possible to create one theory to explain all women's crime and victimization.

In addition to the five commonly discussed feminist perspectives, scholars are including in

their research an examination of the complexities of the intersections of gender, social class, and race. This intersectional approach considers that individuals experience of multiple forms of oppression and how these experiences may influence their actions and reactions.

Historical Overview and Context

Early explanations of criminal behavior were focused almost exclusively on men and boys. The bulk of classical criminological studies used samples of males, often juvenile males, to make conclusions about crime, primarily street crime, and characteristics of criminals. Women were absent from early scholarship as they were not included as part of the samples studied or as scholars developing the body of criminological research. When they were included, women offenders and victims were portrayed in a stereotypical manner or forced to fit within models of male criminality.

This early research did not ask whether explanations of criminal offending developed by studying only males were generalizable to women. One assumption was that any theories developed to explain male crime would also apply to crimes committed and experienced by women. This approach, however, failed to consider that in a gendered social structure men and women have different, unequal experiences. By focusing exclusively on men and boys, criminologists also failed to explain why there was a gap in the number of crimes committed by men compared to those committed by women. Fewer women were committing crime compared to men, and feminist scholars argued that understanding women's criminality could also be beneficial to understanding men's criminality as well.

With the rise of the second wave of the feminist movement in the 1960s and 1970s, the field of criminology began to pay greater attention to women and women's experiences with respect to crime. Feminist scholars questioned the absence of women in explanations of crime, and they were also critical of the limited portrayals of women in criminological theory either as pathological individuals or only engaging in gender-specific crimes such as prostitution.

Furthermore, they began to publish research that considered explanations for the large gender

differences in crime and to question whether the theories developed to explain male crime applied to crimes committed by women. Within a feminist framework, these scholars considered how gender inequality was related to different opportunities or pathways toward criminality for women and they began to study women as offenders as well as victims. Researchers focused on the relationship between victimization and offending. They also examined what types of behaviors were defined as crimes. For instance, focusing attention on offenses such as marital rape and intimate partner violence as crimes, rather than family issues, highlighted some of the unique victimization experiences of women previously not considered. These lines of inquiry opened the door to even more scholarship that considered how to explain differences between men and women with respect to crime.

FETAL ALCOHOL SPECTRUM DISORDER IN THE CRIMINAL JUSTICE SYSTEM

Individuals with fetal alcohol spectrum disorder (FASD) experience a range of physical, cognitive, affective, and behavioral impairments as a consequence of exposure to alcohol during pregnancy. FASD most often occurs in the context of additional mental and physical health difficulties, high rates of early life adversity, and poor developmental outcomes, including contact with the criminal justice system. The high prevalence of FASD in the criminal justice system is concerning for several reasons. There is limited professional awareness and capacity to recognize the disability and the difficulties experienced by many offenders with FASD may contribute to increased recidivism and a revolving door trajectory through the criminal justice system. This entry focuses on the intersection between FASD and the criminal justice system, including background, prevalence, research, screening, diagnosis, and intervention in criminal justice settings.

Characteristics and Diagnosis

FASD was first recognized during the early 1970s as a constellation of developmental abnormalities stemming from the teratogenic effects of alcohol use during pregnancy. Since then, research has clarified a wide range of adverse impacts resulting from prenatal alcohol exposure (PAE). Physical indicators of the disability are present in approximately 10% of affected individuals. These include facial dysmorphology, growth restriction, and physical alterations to the brain. In addition, the majority of individuals with FASD experience significant changes in central nervous system functioning, including problems with working memory, executive functioning, attention, social/adaptive skills, language and communication, academic skills, and sensory and motor skills. Individuals with FASD also experience challenges in learning and understanding cause and effect, poor decision-making skills, immature social skills, suggestibility, and behavioral features such as impulsivity. Evidence suggests high rates of

comorbidity with other mental health disorders, including substance abuse and suicide, along with physical health problems. However, there is considerable heterogeneity in functioning and outcomes among individuals, in addition to personal strengths and resiliencies, necessitating individualized assessments to identify personal strengths and limitations.

A number of approaches to FASD diagnosis have emerged over time, including the Institute of Medicine's guidelines for FAS, the University of Washington's FAS Diagnostic and Prevention Network's Four-Digit Diagnostic Guide, the Canadian guidelines for FASD diagnosis, and most recently, the addition of "Neurodevelopmental Disorder associated with Prenatal Alcohol Exposure" in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*. Terminologies vary by diagnostic system but generally characterize a range of constellations of impacted areas across the spectrum. Examples include fetal alcohol syndrome, partial fetal alcohol syndrome, alcohol-related neurodevelopmental disorder, and static encephalopathy or neurobehavioral disorder, with or without confirmation of PAE. In general, guidelines support a multidisciplinary assessment that spans the spectrum of areas potentially impacted, through a team approach. Unfortunately, there is limited diagnostic expertise across North America, particularly among clinicians with experience and training to conduct evaluations in the criminal justice system context.

Prevalence and Epidemiology

FASD is estimated to affect between 1% and 5% of individuals in North America. It is considered to be the most common preventable neurodevelopmental disability. However, there is considerable worldwide variation in prevalence rates, and higher rates have been demonstrated in vulnerable populations and communities, such as children in foster care. Early research identifying higher rates of FASD in northern Canadian communities and rural communities may have led to the misperception that the disability was linked with a particular ethnic or cultural group. It is important to note that FASD occurs at high rates in areas where the social determinants of health adversely impact women and families, leading to a range of

problems that may increase the risk of alcohol-exposed pregnancies, such as higher rates of addictions, lower engagement in health care, poverty, and homelessness.

FASD and the Criminal Justice System

Among the adverse outcomes experienced by individuals with FASD, overrepresentation in the criminal justice system is likely the most costly and impactful. Limited studies have estimated high prevalence rates, ranging from 10% to 23% in adolescent and adult correctional and forensic settings. A large-scale study of adolescents and adults with FASD found that 60% had experienced contact with the criminal justice system. Canadian youth with FASD are estimated to be 19 times more likely to be incarcerated in a given year compared to those without the disability. These rates far outweigh population estimates for FASD prevalence and are likely underestimates, given an overall lack of awareness of the disability in justice settings, limited access to diagnosis, and lack of routine screening. Currently, there is a strong drive to implement and validate a range of FASD screening tools developed for criminal justice settings that can help to identify individuals at risk of having FASD who require a more extensive evaluation.

Individuals with FASD present with a complex clinical profile that may impact their risk of engaging in illegal behavior. Although empirical data are scarce, reports from clinicians and legal professionals suggest that offenders with FASD have difficulty complying with legal supervision orders, respond poorly to traditional treatment and management strategies, and have higher recidivism rates, leading to a revolving door phenomenon in the criminal justice system. These problems may result, in part, from a failure to identify and provide the support needed to address cognitive deficits and clinical needs linked with offending. FASD may be relevant at various stages of the criminal justice system. Individuals with the disorder may have difficulty understanding and participating effectively in police interviews. They may have poor appreciation of their legal rights upon arrest. Coupled with lower cognitive functioning and social skills deficits, these individuals may be at higher risk of making incriminating statements or false confessions.

Navigating a criminal trial is considered a demanding task for typically functioning defendants and may be particularly difficult for individuals with compromised intellectual functioning. Clinicians working in legal settings may need to consider FASD in the context of a range of forensic assessments required by the courts, including adjudicative capacity, competency to be executed, criminal responsibility, and future violence risk and dangerousness. The court will often consider the role of FASD at the sentencing stage and may order an assessment to understand the role of the disorder in crafting an appropriate sentence, particularly in youth courts, which often takes a more rehabilitative approach. As noted, offenders with FASD may have difficulty complying with legal supervision orders in the community on either probation or parole and are overrepresented in incarcerated settings. Individuals with FASD also experience high rates of victimization and may also have difficulty navigating the criminal justice system as witnesses and victims, requiring additional support.

Research on FASD in the context of the criminal justice system is limited. Several studies have evaluated psycholegal abilities relevant to police interrogation and criminal adjudication in young offenders. In 2014, Kaitlyn McLachlan and colleagues found that young offenders with FASD demonstrated significant impairments in their understanding and appreciation of arrest rights and the adjudicative process at a criminal trial. A smaller pilot study in 2011 by Natalie Novick Brown and colleagues found higher rates of interrogative suggestibility in criminal defendants with FASD, a feature that has been linked with the tendency to acquiesce or give in to questioning during police interviews, along with the provision of false confessions.

Risk and Protective Factors in Offending

Despite a wealth of experiential and clinical information about the experiences and needs of offenders with FASD, research regarding specific factors that contribute to their likelihood of coming into contact with the criminal justice system is limited. As of 2016, only one study, published by Raymond Carrado and Evan McCuish in 2015, explicitly evaluated FASD's role in developmental

and offending outcomes in young offenders. The study retrospectively compared incarcerated youth with FASD (identified based on file review) to a large group of incarcerated young offenders without FASD. Results showed that youth with FASD were more likely to present with risk factors related to offending, including a history of placement in foster care, the presence of comorbid behavioral disorders, low self-control, a negative self-identity, and an earlier first age of alcohol use. However, after controlling for identified risk factors, the FASD diagnosis no longer accounted for early onset and frequent offending, leading authors to suggest that the presence of additional risk factors were most salient in predicting offending outcomes. A 2018 study by McLachlan found that young offenders with FASD recidivated more rapidly during a 1-year follow-up period compared to those without FASD. They also presented with fewer protective factors or those factors that decrease an offender's likelihood of engaging in future violence or offending, which was associated with higher recidivism rates.

Anne Streissguth and colleagues' seminal research on adolescents and adults with FASD highlighted the importance of protective factors in reducing adverse outcomes for individuals with FASD. They found that a stable, nurturing home and younger age at diagnosis were important protective factors linked with lower risk for trouble with the law. Two qualitative studies were also published in 2016 wherein individuals with FASD, as well as professionals who work with the population, were interviewed about risk and protective factors. Jacqueline Pei and colleagues found that participants identified hope, willingness to change, and resilience as key protective factors linked with more positive outcomes. Beth Anne Currie and colleagues found that early diagnosis and lower substance abuse appeared to be associated with reduced justice contact. Overall, there is a need for FASD-related research in criminal justice settings.

Screening, Assessment, and Diagnosis in Legal Settings

In general, screening for FASD at all stages of the criminal justice system is lacking. A number of screening tools have been developed with the aim of identifying justice-involved individuals at risk

of having FASD; however, none have been prospectively validated for use across settings. In addition, most screening instruments rely heavily on the availability of information about an individual's developmental history and functioning, which may be difficult to obtain in many settings and when working with adults. Research indicates that professionals working at all levels of the criminal justice system do not have enough awareness, understanding, and training to identify and support individuals with FASD. There are currently limited assessment and diagnostic opportunities in both juvenile and adult criminal justice settings (e.g., jails, forensic psychiatric facilities).

There is a general consensus that more opportunities for mental health and cognitive assessment, including FASD assessments, are needed for justice-involved individuals with PAE. However, FASD diagnosis is challenging in this population for a number of reasons, particularly as offenders reach adulthood. Individuals in the criminal justice system tend to experience high rates of subsequent adverse events that may contribute to further mental health and cognitive problems, such as head injury, substance abuse, trauma, and poor health care and nutrition. These may cloud the diagnostic picture in the context of PAE. In addition, it may be difficult to confirm PAE as people age due to limited availability of collateral informants (e.g., biological mother may be deceased) and a historical tendency to not document information about PAE in records.

Interventions

Research on interventions for offenders with FASD is limited, and consensus from an evidence-based perspective regarding the best treatments or programs offenders with FASD has yet to be reached. However, evidence suggests interventions that adhere to the popular Risk-Needs-Responsivity criminal justice intervention theory are effective in a wide range of offender populations and may prove helpful in the evaluation of programming for offenders with FASD. The Risk-Needs-Responsivity model posits that the most intensive intervention resources should be directed toward offenders with the highest level of risk, that interventions should address identified needs, and that interventions should be delivered in a manner that

is responsive to the capacities of each individual. The responsivity arm of the Risk-Needs-Responsivity model is likely to be particularly key for offenders with FASD, given the complex cognitive and behavioral features that may impact their ability to benefit from traditional correctional intervention strategies without modification.

FIELD TRAINING FOR CRIMINAL JUSTICE CAREERS

Professionals in criminal justice careers are tasked with making complex moral and legal decisions while demonstrating sound judgment and

reasoning. Field training programs are one of the ways in which criminal justice agencies train, educate, evaluate, and prepare criminal justice professionals for these vital positions. Field training programs are designed to guide new officers, agents, deputies, and other individuals in law enforcement professions in developing a working and functional knowledge of laws, codes, case law, procedures, policies, directive systems, interpersonal communication, investigation, emergency and nonemergency response to a variety of calls for service, corrections processes, law enforcement and organizational culture, and other aspects of criminal justice careers.

This entry focuses on field training for careers in criminal justice, including the need for effective field training techniques and programs, the historical context of the development of field training, the major field training models, and major issues incorporated into field training since the development of structured field training programs.

Effective Training

Properly selecting, effectively training, and adequately supervising criminal justice professionals are moral and legal obligations of all criminal justice agencies. Failing to provide effective training or providing improper training to law enforcement officers are among the liabilities to agencies and to supervisors in criminal justice professions, particularly when the training or lack of training is causally linked to a constitutional violation.

Field training programs developed and continue to evolve and improve as a result of legal, social, and political influences. Law enforcement agencies recognized deficiencies and liabilities of relying solely on on-the-job training. This reliance resulted in the advancement of training programs designed to address these concerns. Increasingly effective training in criminal justice fields has incorporated adult learning techniques into structured programs.

Although no one theory or model defines how adults learn effectively, a number of principles have been identified as producing better results when training adults in criminal justice fields. A focus on how individuals learn effectively has overtaken the prior training approach. Previously,

individuals were offered a single way to learn as determined by a representative of a particular agency. Failing to adjust to whatever lessons were presented by the agency would result in failing to assimilate or perform. Failing to assimilate or perform would often result in separation from the agency.

In the 1980s, research began to emerge regarding effective ways to present education and training to adult learners, which would later be applied to training in criminal justice fields. The multidimensional nature of adult learning, also referred to as *andragogy*, suggests that the context of an individual's cultural background, interpersonal dynamics, relationships, individual strengths, individual challenges, and individual learning style interrelates in how an employee will successfully learn.

Among the more effective and transformational learning methods is self-directed learning in which the learner makes decisions, engages in, and takes responsibility for the learning process. Within professional criminal justice training methods and programs, the successful learner will learn through experience, learn in a way that is personally relevant, and learn through problem-centered rather than content-oriented training.

Field training programs reflect the intersection of criminal justice professions and the study and management of human behavior. Field training programs have been developed and continue to evolve to effectively train and evaluate newly hired law enforcement professionals and to assimilate these employees into law enforcement professions and their specific agencies' cultures. Field training programs often serve as a probationary period for employees, during which employees are subject to both training and evaluation by instructors to determine suitability to a particular law enforcement or criminal justice position.

History

In the early 20th century, August Vollmer, chief of the Berkeley Police Department in California, defined and organized several areas of policing, including creating a police school. This school would initiate the formalization of police training and police academies. Other agencies began to follow this trend in organizing police training within

state, county, municipal, educational facilities, and other law enforcement jurisdictions. Although there was no uniform training method or model among the agencies, many agencies sought to create or refine structured training programs. Two of the major field training models that developed from this transformation are the San Jose Model and the Police Training Officer (PTO) Model.

San Jose Model

Field training in law enforcement was predominantly informal and unstructured prior to the introduction of the first major field training model, San Jose Model, sometimes referred to as the *Kaminsky model*, which arose from the San Jose California Police Department. Prior to the 1970s, when law enforcement officers completed an academy, they were provided minimal training. This training often amounted to a brief orientation to specific skills and basic departmental procedures prior to being released to work independently.

Two missing components of effective training were identified that the San Jose Model attempted to address: evaluation and mentoring. Without a formal and consistent training officer, a new officer would not have an experienced and knowledgeable officer who could offer him or her valuable advice and knowledge. Moreover, without a formalized system of evaluation and accompanying documentation, a law enforcement agency could easily fail to identify and correct an employee's weaknesses. Secondarily, an agency could fail to identify major performance deficiencies on the part of an employee that would result in a trainee's severance from the agency.

The San Jose Model was designed to organize the learning process into four phases of training that incorporates adult learning principles, standardized performance guidelines, and standardized evaluation. Standardized evaluation is produced through daily observation reports prepared by training officers as well as periodic evaluations prepared by supervisors. The phases were designed to associate stages of learning with the requirement to perform basic tasks and dependence on the trainer, then later more complex tasks and independence. The fourth and final phase was designed to document the

trainee's performance from an observation perspective of the training officer as the trainee performs as a single, independent law enforcement officer. The San Jose Model stood as the leading and standard field training and evaluation model for more than three decades and is still utilized in many current law enforcement and other criminal justice training programs. In addition to its use by law enforcement agencies, the San Jose Model was adapted for application to other criminal justice positions such as probation officer, corrections officer, game warden, and park ranger.

PTO Model

In 1999, the Reno Nevada Police Department and the Police Executive Research Forum set out to develop an alternative field training model that incorporated problem-solving methods and community policing methods into the existing realm of field training. The PTO Model, also called the *Reno model*, sought to address the lack of two areas in existing field training programs. These areas were identified as fundamental, ongoing change in criminal justice professions, and protection against liability through an emphasis on effective training and education.

Like the San Jose Model, the PTO Model also utilizes several training phases, beginning with an integration phase, followed by a phase focused on nonemergency incident responses, then emergency incident responses, patrol activities, and criminal investigation. Trainers using the PTO Model document evaluations of the trainee through the trainee's completion of daily journal entries documenting his or her observations and self-assessments, through *Coaching and Training Reports* completed by training officers each week, the completion of problem-based and community-based exercises, and midterm and final evaluations.

Police academies and field training programs continue to evolve in ways that reflect increasingly meaningful and effective structure, curriculum, and the delivery of information using a variety of learning styles. The PTO Model is applied to many criminal justice positions as well, such as communications, detention officer, and game warden.

Field Training Advancement

Law enforcement training will continue to update practices related to improved tactics; however, revolutions in police training also reflect the advancement of law enforcement as a profession. As field training programs in criminal justice fields continue to evolve, they incorporate these more complex and sophisticated training issues that reflect the needs and principles of the communities' agencies and serve the values of society as a whole. As social problems and priorities evolve, criminal justice as a discipline must also progress. Among these advancing tenets in fields of criminal justice are ideals surrounding community policing and procedural justice.

Community Policing

An orientation to community policing and community problem-solving has been introduced into the training programs in law enforcement professions, as noted in the PTO Model phases. Beyond the technical skills, procedure and policy knowledge, and knowledge surrounding ordinances and laws, professionals in criminal justice are expected to be a part of and engage with the community in which they serve.

Among the pillars of community policing are community input and influence into agency priorities and policies, developing trust between the citizens and police department, and a focus on crime prevention and law enforcement issues that relate to citizens' quality of life. Community policing requires the recognition of the role a community plays in the authority granted to the criminal justice system, and a balance of crime control and prevention with the relationship criminal justice professionals have with the community. These concepts have been incorporated to varying degrees and in various ways in field training programs, such as in the communication and problem-solving-related standards of the San Jose Model or the community-based exercises incorporated into the PTO Model.

Procedural Justice

Similar to the integration of community policing principles in field training, the principles of procedural justice, or the perceived

fairness citizens experience in the criminal justice processes, have become integrated in various ways into existing field training programs. The concept of procedural justice is tied to the perception of the justice of the process, rather than the perceived justice of the outcome of a situation addressed by the criminal justice system.

The principles of procedural justice are applied to many facets of criminal justice careers. These include a sense of having a voice, a belief they are being heard, and a perception that they are being treated with respect and dignity throughout the criminal justice process, that decisions are made with neutrality and are free of bias, the process is understandable, and perception of helpfulness and interest members of the criminal justice system take in resolving the problem. Concepts of procedural justice have become incorporated into the values and field training in many field training programs within the criminal justice professions as well.

This process of continual evolution of field training programs echoes the importance of the acceptance and assimilation of society's values into field training programs for each of the criminal justice professions and into the criminal justice system as a whole. Where field training once failed to exist, training programs in criminal justice professions have progressed and evolved to reflect the needs and priorities of the people criminal justice professionals serve.

FORENSIC APPLICATIONS IN THE CRIMINAL JUSTICE SYSTEM

The criminal justice system in the United States has in effect become a second public mental health system. A large percentage of persons in U.S. jails and prisons have serious mental illness, substance abuse issues, intellectual disabilities, or a combination of these. In many states, jails in large cities house more persons with serious mental illness than can be found in state mental health facilities. A principal reason for this expansion of persons with mental illness in the criminal justice system stems from inadequate resources at the community and state levels for public mental health care. Although some persons with mental illness commit serious crimes, often individuals with mental illness are arrested for an array of nonviolent offenses such as trespassing, loitering, minor drug offenses, and similar crimes that are related more to the defendant's mental illness than with criminal intent. Once such an individual is in the criminal justice system, however, a number of forensic

issues frequently arise relating to the defendant's mental state. This entry reviews issues pertaining to serious mental illness at several points in the criminal justice process including apprehension, diversion of offenders, competency to stand trial, competency in other contexts of the criminal process, the insanity defense, and diminished capacity.

Apprehension

Typically, law enforcement officers have substantial discretion at the scene of a possible crime either to make an arrest and transport the alleged perpetrator to jail or—if mental illness is suspected—to apprehend the individual for the purpose of transporting the person to a mental health facility for an evaluation. This type of emergency detention allows law enforcement officers to make an on-the-scene decision to pursue an emergency detention for a mental health evaluation and possible services rather than making an arrest. Often, given inadequate resources for an effective public mental health system, law enforcement officers are the first responders to situations in which a person with mental illness is in crisis. In response, many cities and counties have developed Crisis Intervention Team programs to better assist law enforcement in responding to calls involving possible mental health issues. With Crisis Intervention Team training, officers are better positioned to make decisions at the scene of alleged crimes and to respond to situations involving persons with mental illness who are in crisis. Successful implementation of a Crisis Intervention Team program or the use of specialized mental health deputies can frequently result in avoiding the criminal justice system altogether by diverting the individuals directly into mental health crisis services.

Diversion of Offenders

Many jurisdictions have developed programs and implemented policies to identify—and divert into treatment programs—persons with serious mental illness who have entered the criminal justice system and charged with relatively minor, nonviolent offenses. There are a wide variety of such programs including mental health courts, specialized mental health public defenders offices, and mental

health dockets. An important first step toward the success of these programs is a thorough mental health screening at the jail subsequent to the defendant's arrest. Jail officials should also conduct data searches to identify whether the detainee has received or is then receiving mental health services from the state's public mental health system. Many alleged offenders with mental illness have previously received mental health services, whereas others will be diagnosed for the first time in the jail. Correspondingly, it is important that the jail provide mental health care, including appropriate medications. If the arrestee with mental illness refuses medication, that raises other legal issues, and many states have a process for allowing the state to seek a court order regarding the administration of medication.

In many of the successful diversion programs, after a defendant is identified as a person with mental illness, the court will appoint defense counsel who has received specialized training in mental illnesses and mental health law. Correspondingly, in jurisdictions that operate mental health courts or specialized mental health dockets, the presiding judges undertake a central and critical role. As with other specialized courts such as drug courts and veterans' courts, the judge is not strictly operating in a traditional, adjudicatory role. Rather, the judge facilitates regular status sessions that include all the key players: defendant, prosecutor, defense counsel, and members of the treatment team. Although there are many variations among jurisdictions that employ specialized mental health courts or dockets, typically participants volunteer for the program and agree to participate in outpatient mental health services for an extended period (including agreeing to remain compliant with prescribed medications). In exchange for participation, either all charges will be dropped or the court will defer adjudication contingent on successful completion of the prescribed program. Perhaps the most important aspect leading to success in these programs is the active participation of the presiding judge. At the regular status sessions, the judge typically inquires about matters such as whether the defendant has attended scheduled outpatient appointments and has been taking prescribed medications. These programs have largely contributed to lower recidivism rates and longer periods of engagement in

mental health services for the populations served, and it is anticipated that more jurisdictions will develop comparable programs.

Competency to Stand Trial

A defendant must be competent to stand trial. Under the U.S. justice system, this means that the defendant must be able to have a rational as well as factual understanding of the proceedings that are being conducted against the person and be able to consult in a meaningful manner with the person's attorney with a reasonable degree of rational understanding. It is important to note, however, that a lack of competency is not a defense to the underlying crime but instead is a necessary predicate to allowing criminal proceedings to begin or continue. If there is evidence prior to trial to suggest that the defendant might be incompetent to stand trial due to mental illness or an intellectual disability, the court must order that the defendant undergo a competency evaluation. (Issues with regard to the defendant's competency can also arise during the course of trial, which will also result in the need for a competency evaluation.) Usually, a competency evaluation is conducted by a psychologist or psychiatrist with appropriate forensic training and experience. Often, experts are preferred or required to have certification or special qualifications in forensics from the American Board of Professional Psychology or the American Board of Psychiatry and Neurology. In addition, most jurisdictions require that the examining expert not be involved in the defendant's treatment but instead be independent.

As part of a competency examination, the forensic expert is generally tasked with exploring the capacity of the defendant to be able to rationally understand the pending charges and their potential consequences; to converse with counsel about relevant facts and legal strategies; to recognize the various participants in a judicial proceeding and to understand the adversarial nature of the proceedings; and to exhibit appropriate courtroom behavior and to testify, if desired. The forensic examiner also determines whether the defendant has a mental illness or intellectual disability and the degree by which any such disability has a bearing on the defendant's capacity to communicate

with counsel in a meaningful manner and understand the proceedings. In the case of a defendant with mental illness, the forensic expert should also identify whether the defendant is either taking previously prescribed medications or whether appropriate medications are necessary to ameliorate the symptoms of the defendant's mental illness to permit a restoration to competency. In most jurisdictions, statements made by the defendant during the competency evaluation are generally not admissible in later court proceedings except for any hearing or trial on the question of the defendant's competency to stand trial or in other situations in which the defense first introduces evidence regarding the defendant's mental state.

Upon concluding the examination, the forensic expert prepares a detailed report for the court. This report should do more than simply present the expert's conclusion as to whether or not the defendant is competent to stand trial. Instead, in the report, the expert documents the procedures undertaken during the examination and details clinical observations, findings, and conclusions, along with support for those findings and conclusions. In matters involving a defendant with mental illness or intellectual disability, the report should also document the symptoms and deficits relating to the disability and, in the case of a defendant with mental illness, the likelihood of restoration of competency with appropriate treatment for the symptoms of the illness.

If the defense has also raised an issue regarding the insanity defense, there will need to be one or more forensic evaluations conducted on the question of the defendant's sanity at the time of the events that resulted in criminal charges. Some jurisdictions require that different forensic experts be appointed to conduct the competency and insanity examinations. In other states, the court may initially appoint the same expert to conduct both the competency examination and the insanity examination. If the expert concludes that the defendant is competent to stand trial, then the expert may proceed to examine the defendant with regard to insanity. If, however, the examiner concludes that the defendant is *not* competent to stand trial, the expert may not continue with an examination on the question of the defendant's sanity. This is critical because once there has been

a determination that the defendant is not presently competent, anything further that might be shared with the examining forensic expert would be suspect and likely unreliable.

Following the competency evaluation and upon the defendant's return to the court, the court will generally proceed with competency proceedings. In most jurisdictions, the court will conduct a competency hearing without a jury; however, some jurisdictions allow a defendant to demand a jury trial solely on the question of competency. In such a case, it cannot be the same jury that will determine guilt or innocence of the underlying criminal charges because the focus is solely on the defendant's competency to stand trial. If the court concludes that the defendant is incompetent to stand trial, then the court will order that the defendant be transported from the jail to a mental health facility for competency restoration treatment. For nonviolent offenses, many jurisdictions also provide an option for outpatient competency restoration treatment. Upon restoration of a defendant's competency, the defendant will be returned to the court's jurisdiction and the criminal proceedings may resume (whether that is a trial or the entry of a guilty plea). A frequent problem in many jurisdictions, however, is that defendants with mental illness are restored to competency at a mental health facility (often with medication treatment) but then relapse upon returning to the local jail and awaiting trial. Many times, there can be a lack of continuity of care after the defendant's return to the jail and during the time lag before the criminal proceedings resume. This raises the prospect that the defendant will again be incompetent to proceed to trial, and additional competency evaluations and proceedings will be necessary.

Competency in Other Contexts of the Criminal Process

In addition to competency to stand trial, a criminal defendant's competency is relevant in several other contexts in the criminal justice system. First, a defendant must be competent to plead guilty to criminal charges. This is significant because over 90% of all criminal prosecutions in the United States are resolved by plea agreements. If a defendant is incompetent to enter a guilty plea, the

adjudication may be subject to later challenge. Accordingly, it is important that a defendant with mental illness who is in need of treatment receive appropriate services, including necessary medications, to ensure that the symptoms of the defendant's mental illness have stabilized and that the defendant not only is competent to stand trial but also is capable of agreeing—competently—to any guilty plea.

Second, a defendant must be competent to exercise a choice to waive the presence of counsel and to proceed to trial without representation. If the defendant is incompetent to make such a critical decision, but the court nonetheless allows the trial to proceed in the absence of defense counsel, the resulting trial and its outcome may be subject to reversal.

Finally, a defendant who has been adjudicated guilty of a capital crime and who faces the death penalty must be competent to be executed. A defendant on death row who has a serious mental illness might become incompetent, particularly if the defendant's mental illness is not being treated. Ethical issues can arise for both forensic psychiatrists and attorneys in such a situation. The psychiatrist will recognize that medication is appropriate to treat the symptoms of the person's mental illness, but that the treatment will likely result in restoring the defendant's competency to then be executed. Can that doctor ethically support a state's effort to order forced medication in such situation? The defendant's counsel will also likely recognize that medication is in the defendant's best interest with regard to treating the symptoms of the individual's illness but ethically must oppose attempts by the state to order forced medication because of the likely restoration of competency for execution. One state, Maryland, has enacted legislation to require the courts to commute the death sentence in such a situation to life in prison without the possibility of parole.

Insanity Defense and Diminished Capacity

Insanity Defense

Most states permit a defendant to plead and attempt to prove legal insanity as a defense to crimes. The formulations of the insanity defense vary, however, among these states.

Many jurisdictions require the defendant to prove that because of mental illness or intellectual disability, the defendant should not be found guilty of the charged crime because the defendant did not know or appreciate that the conduct resulting in the criminal charges was wrong—a cognitive test. Other states also allow juries to make a volitional inquiry. In those states, the defendant can succeed with the defense by showing that because of mental illness or intellectual disability, the defendant lacked the capacity either to appreciate the wrongfulness of the defendant's conduct or to conform the defendant's conduct to the requirements of the law.

Contrary to popular myth, the insanity defense is not raised frequently, and it is relatively rarely successful. It is invoked far less commonly than issues regarding a defendant's competency to stand trial, yet when it is raised in a high-profile case, there is often significant publicity. For example, following the much-publicized insanity acquittal of John Hinckley Jr. for the attempted assassination of President Ronald Reagan in 1981, many state legislatures and the U.S. Congress enacted laws that narrowed the scope of their respective insanity defenses.

Unlike other defenses to crimes, such as self-defense, an insanity acquittal does not typically result in the defendant's leaving the courtroom as a free person. Instead, there are usually follow-up judicial proceedings that lead to long-term, court-ordered hospitalization for mental health services, with periodic judicial review of the commitments.

In general, defense counsel will typically only raise the insanity defense in cases involving very serious crimes. This is due in part because for lesser offenses, plea agreements can lead to comparably shorter sentences without the uncertainty of long-term hospitalization following an insanity acquittal. Moreover, raising the insanity defense can be an expensive proposition given that testimony from forensic psychologists or psychiatrists is critical to informing and persuading the jury about the defendant's mental illness and its impact on the defendant's cognitive state at the time of the events in question. At times, however, the defense can be raised successfully when it is not vigorously opposed by the prosecutors, often when they have reached a conclusion that

long-term hospitalization serves the ends of justice, as opposed to lengthy incarceration.

Diminished Capacity

Related to the insanity defense and recognized in some states is the defensive theory of diminished capacity. Under this defense, a defendant is allowed to introduce evidence regarding the defendant's mental state at the time of the events for which the charges are pending to negate the mens rea necessary for the state to obtain a conviction. For example, suppose that a defendant intentionally fires a gun at a police officer but misses. The state then prosecutes the defendant for the crime of attempted murder, which among its elements requires the state to prove that the defendant intended to kill the victim. But, suppose that due to the symptoms of the defendant's mental illness, the defendant believed that he was shooting at a zombie. In such a case, the evidence could be introduced under a diminished capacity defense as an attempt to negate or disprove that the defendant had the requisite mental state of intent to kill another person. Some states do not allow such a defensive theory, however, and require any type of evidence relating to mental illness to be introduced as part of pleading and proving an insanity defense. In contrast, however, in those states that do not provide for an insanity defense, the ability of a defendant to introduce mental state evidence to negate the mens rea necessary to prove a crime is nonetheless constitutionally required.

FORENSIC ASSESSMENT OF OFFENDERS

Forensic assessment is the evaluation of an offender's mental health or psychological functioning in order to answer a specific question posed by the legal system. The law sometimes allows and/or mandates different responses from the system as a result of an offender's cognitive and mental health functioning. For example, the U.S. Supreme Court has ruled that it is unconstitutional to execute a person with intellectual disability. Evaluation of an offender's diagnosis or functioning in a situation such as this needs to be completed by qualified mental health professionals, making forensic assessment one of the clearest intersections between psychology and the law. This entry details the differences between forensic assessment of offenders and general mental health assessment and introduces common types of forensic assessment.

The Forensic Assessment Context

The Referral Source

Forensic assessments seek to answer a specific question about an offender's psychological functioning that has bearing on his or her legal case. These questions are sometimes referred to as *psycholegal* questions as a result. It is the fact

that a question is being answered for the court system, not the fact that an offender is being evaluated, that makes an assessment a *forensic assessment* and most clearly distinguishes this area from general mental health practice. It is often stated that the legal system, rather than the offender, is the client of a mental health professional completing a forensic assessment. Although a mental health professional who is providing treatment for an offender may be called upon to provide and/or testify relevant treatment information, this would not be considered a forensic assessment as the therapist's focus has been on meeting the offender's treatment goals, not addressing the questions of the court. Therapists are generally discouraged from completing forensic assessments of their clients. This is because forensic assessments require a level of objectivity that is difficult to obtain once one has provided treatment to an offender. There are also conflicting expectations and obligations to the offender in each type of assessment that may be difficult for a therapist to reconcile as discussed later in this entry.

The Ultimate Issue Debate

While the defining feature of a forensic assessment is answering a psycholegal question, there is some conflict within the field as to how an evaluator should answer the question. Mental health professionals complete forensic assessments to assist the trier of fact in reaching a decision. The trier of fact is a judge or jury and it is their responsibility to decide the outcome of a case or what is often referred to as *the ultimate issue*. Determining if an offender was legally insane at the time of an offense and therefore not guilty or such a danger to the community that he or she should be removed from it are examples of ultimate legal issues.

The extent to which forensic evaluators should speak directly to ultimate issues is debated. On one side, some argue that mental health professionals are not experts in the law or afforded the right to make moral decisions about its enforcement that society gives judges or juries. For example, most jurisdictions generally define legal competency as the ability of defendants to understand charges against them and assist their

lawyer in their defense. The ultimate issue before the court is whether they are able to do this to a *subjectively determined* reasonable level. Those who believe that forensic evaluators cannot or should not determine this level instead urge them to conduct an assessment that addresses specific areas of functioning related to this ability while not making a conclusive statement about the offender's competency. Others see the issue quite differently. They argue that mental health professionals do indeed have specialized knowledge that allows broad conclusions to be made (though the trier of fact can still choose to accept or reject them). Moreover, it may be confusing to a jury why an evaluation would be requested and completed if not to answer the question posed.

Restrictions on ultimate issue testimony may vary across evaluation type and jurisdiction. For example, in the United States, Federal Rules of Evidence explicitly prohibit conclusions as to the mental state at the time of an offense while not barring such testimony outright in other types of cases. Case law indicates some inconsistency in the application of this rule, however, and evaluators and legal observers may find varied outcomes of objections to ultimate issue testimony in individual cases.

Other Unique Aspects of Forensic Assessment

Role of the Evaluator

The task of answering specific psycholegal questions is not the only thing that distinguishes forensic assessments from general mental health assessments. The most obvious difference is that of the role taken on by the evaluator. In general mental health assessment, a mental health professional generally adopts a therapeutic stance focused on improving or enhancing an individual's functioning or quality of life. In forensic assessment, the evaluator's primary goal of answering a psycholegal question requires an objective stance as to the long-term outcome for the offender. Indeed, determining that an offender has the abilities needed to stand trial may ultimately result in conviction, and the result of a competency to be executed evaluation may clear someone for death. It should be noted that adopting an objective stance for the

purpose of the evaluation does not mean that forensic assessments are done without respect for the offender and his or her rights. In fact, evaluators may need to be particularly skilled at developing rapport and eliciting information from offenders.

Response Style and Suspected Malingering

Self-reports are highly valued in general mental health evaluations, and the information provided by a person is generally believed to be valid. Forensic evaluators incorporate self-report information but are generally trained to collect multiple sources of data and often see self-reports as no more important than other types of information. In fact, some degree of defensiveness resulting in inaccurate portrayals of functioning is expected from offenders, and some have called for routine evaluation of possible malingering, or intentional feigning of psychiatric symptoms for secondary gain, in all forensic assessments. In forensic assessment, the concern is frequently that offenders may be motivated to avoid legal consequences for their actions by presenting themselves as affected by a mental illness.

Confidentiality and Information Sharing

The information provided in general mental health assessments is confidential, with major exceptions involving suspicion of child abuse or neglect and disclosure of information related to threats of grave harm toward self or an identified other. An offender is not typically afforded any confidentiality in forensic assessments and will need to be properly informed of this before being evaluated. As a result, many may be reluctant to participate, though they are typically court-ordered to do so.

The demands placed on the forensic evaluator are great, particularly as establishing rapport and gathering data from an offender and others in his or her life often needs to be completed quite rapidly and by deadlines set by the court system rather than the evaluator. The results of forensic assessments may be provided to the court as written report and/or oral testimony in which the evaluator is subject to questioning by both the prosecution and the defense.

Specific Forensic Assessments

Competency to Stand Trial

The Psycholegal Question

Competency to stand trial evaluations is one of the most common forms of forensic assessment. It has long been believed that a justice system that does not allow defendants to properly defend themselves would be inherently unfair. In the United States, this belief is illustrated in the *Dusky* standard, referring to the 1960 legal decision of *Dusky v. United States*. This decision formally operationalized competency to stand trial as the ability to

1. consult with an attorney to a reasonable and rational degree, and
2. hold a rational and factual understanding of the charges one is facing.

Deficits in one or both areas may result in a finding of incompetency to stand trial. The question that evaluators seek to answer therefore centers on an offender's cognitive abilities as they relate to these two areas. Given that the legal system also has a mandate to bring cases to trial, an attempt to restore incompetent offenders to competent states is often made, and evaluators may also be asked to speak to the likelihood of this happening. For example, incompetency due to the acute symptoms of schizophrenia may be alleviated by appropriate medical treatment while incompetency due to an extremely low IQ associated with an intellectual disability will not.

The Assessment

The assessment of competency focuses on a defendant's current functioning and abilities. Evaluators may assess for the presence of specific mental health disorders, but a psychiatric diagnosis alone is not enough to qualify one as incompetent. Evaluations will typically involve an interview of the offender including behavioral observations that may be relevant to his or her ability to work effectively with a lawyer. Psychological testing may be used as well. General psychological testing measures may be used to the extent they provide information bearing on the abilities needed for competency. Formal intelligence testing, for

example, may be relevant to present reasoning abilities as well as restorability to competency as described earlier while broader personality measures have little utility.

Several tests have also been developed that specifically assess competency to stand trial. These are considered forensic assessment instruments as they are used only in forensic assessments to help answer specific psycholegal questions. Use of forensic assessment instruments in competency evaluations may increase the objectivity and reliability of conclusions. It is important to note that these instruments vary in their format and level of detail. Brief screening instruments are intended to rule out incompetency and avoid unnecessary full-length evaluations. Other measures aim to fully assess competency-related abilities by directly questioning legal knowledge and reasoning or exploring defendant's answers to questions about these issues as they relate to hypothetical vignettes. Other competency measures are actually more similar to structured interview guides that allow evaluators to organize their questioning.

Controversies and Issues

Most offenders evaluated for competency to stand trial will be found competent. Thus, incompetency is a low base rate event. Low base rate events are difficult to study as adequate samples are hard to generate. They are also hard to predict as rare events are associated with high rates of false-positive conclusions. It is important to understand that competency measures are not *tests* that definitively detect the absence or presence of legal competency. All psychological instruments have some degree of measurement error. Thus, the error rates of tests must be considered and appropriately conveyed to the trier of fact. While assessment measures have an advantage over unstructured clinical judgment in this regard, the legal system must determine what level of error is acceptable for itself.

A related issue is the competency of minors. Age and immaturity, by themselves, may render some youthful offenders incompetent. Many believe that developmentally sensitive measures of competency must therefore be used, though few are available. Competency evaluations of juveniles using measures developed for adults should include a caveat about their applicability.

Competency to Be Executed

The Psycholegal Question

As with many areas of forensic assessment, a legal decision carved out an area of practice. In 1986, the U.S. Supreme Court ruled in *Ford v. Wainwright* that executing someone who is criminally insane is a form of cruel and unusual punishment and therefore unconstitutional. *Insane* is a legally defined term and not a very well defined one at that time. As it relates to competency to be executed, the word *insane* bears more similarity to competency to stand trial than being so impaired by mental illness so as to not be held responsible for one's actions (see Criminal Responsibility section in this entry). The Supreme Court did not set a specific competency standard in *Ford* or the related 2007 case of *Panetti v. Quarterman*. Nevertheless, the decisions have been interpreted together to suggest that defendants must have both factual and rational understanding of their impending execution. In other words, offenders must know that they will be executed and understand that this is punishment for a crime they have been convicted of. For example, an offender who understands that he or she will die but harbors persecutory delusions for the reason why may be incompetent.

Specific competency standards vary across individual states as a result of the ambiguity of the Supreme Court decisions in *Ford* and *Quarterman*. In some jurisdictions, an offender must also be able to self-advocate by communicating reasons why the punishment might be unjust. It is important to note here that *having* the ability to do this is not the same as doing it and an offender who chooses not to utilize available appeals or legal avenues to avoid execution is not automatically incompetent if it is determined that he or she made a rational decision not to do so.

The Assessment

Evaluation of competency to be executed is quite rare, and as a result, there is limited research in this area. Although competency issues may have been raised earlier in a defendant's case, assessment of competency to be executed should involve consideration of the defendant's *current* required abilities, which may vary depending on the jurisdiction where the evaluation is completed in as

noted earlier. While this remains one of the most controversial areas of forensic assessment, there is a consensus that such evaluations should include an interview with the offender and those individuals familiar with him or her (e.g., family, lawyers, prison staff, treatment providers). Checklists and interview guides have been developed by some authors, though norm-referenced assessment measures are not available.

Controversies and Issues

Additional research to guide practice in this area is needed but difficult given the limited number of evaluations that are completed. These assessments are also notable for the ethical issues they present. A finding of competency in essence *clears* an offender for execution. As mental health professionals, forensic evaluators may find this incompatible with ethical mandates to *do no harm*. There are also concerns that personal views on capital punishment may introduce bias into this form of assessment. These ethical conflicts may be strong even in jurisdictions that do not require evaluators to speak to the ultimate issue in these cases.

A finding of incompetency brings additional ethical conflicts if attempts are made to restore an offender to competency, often with the use of forced psychiatric medication. These ethical issues have resulted in organizations such as the National Commission on Correctional Health Care prohibiting correctional treatment providers from participating in competency to be executed evaluations and urging that they instead defer to independent evaluators.

Competency to Waive Miranda Rights

The Psycholegal Question

Making incriminating statements to police during an interrogation or confessing to a crime may appear to make a criminal trial more straightforward and this may prove true, unless a defendant asserts that he or she was not competent to do so. The Supreme Court case of *Miranda v. Arizona* (1966) clarified that police must inform suspects of their right to remain silent during questioning and to consult with a lawyer. It must also be clear that the information that the suspect provides can

be used against him or her and that the interrogation can be stopped at the suspect's request. Competent waiver of one's Miranda rights requires that a defendant does so in a manner that is *knowing, voluntary, and intelligent*. In other words, one must understand that he or she has specific rights, comprehend the implications of these rights, and waive them without coercion or due to extreme distress. Decisions about the admissibility of evidence in cases of contested competent Miranda waivers are typically made by considering the *totality of circumstances* with multiple factors possibly relevant, including those within the individual (e.g., intelligence and history of contact with law enforcement) and the nature of the interrogation (e.g., prolonged or coercive). As a result, assessments may be quite broad in scope.

The Assessment

Unlike the other competencies reviewed in this entry, assessment of competency to waive Miranda rights is retrospective. If available, review of a recording or transcript of the waiver and subsequent interrogation is therefore quite important. Given the importance of understanding and reasoning about one's rights, formal assessment of intelligence and academic achievement is essential in many cases. Deficits in these regards are neither necessary nor sufficient for incompetency, however, as it is possible that factors other than intellectual limitations (e.g., extreme stress or symptoms of a mental disorder) could also impair understanding or reasoning. Individuals of limited intelligence may also give competent waivers if they are appropriately informed and counseled of their rights in a manner that matches their abilities or if prior contacts with the legal system are believed to have provided adequate *education* about their rights.

Forensic assessment instruments have been developed to specifically assess the abilities to make competent Miranda waivers and may be used in addition to tests used to determine intelligence, mental disorders, or personality traits that may make one susceptible to undue influence or coercion.

Controversies and Issues

Juvenile offenders present with unique issues related to Miranda waivers. Jurisdictions vary in

regard to whether minors may waive their rights for themselves or require parents to do so for them. While one would assume most parents have their child's best interests in mind, *incompetency by proxy* may be a real issue if parents have their own intellectual or other impairments in understanding or reasoning as described earlier.

Criminal Responsibility

The Psycholegal Question

If defendants can prove that they did not commit a crime, they will be found not guilty. However, even those who admit to a crime may be found not guilty if they lack criminal intent or *mens rea*. This long-held legal tradition was formally operationalized, in 1843, in England and is now known as the *M'Naghten standard*. Briefly, the standard holds that a defendant may be found *not guilty by reason of insanity* if a mental problem prevents one from knowing what he or she was doing or that it was wrong. Various criticisms and adaptations of this standard have been proposed over time. A more modern iteration was made in 1962 by the American Law Institute, which suggested that people should not be held responsible for a crime if they do not understand that their actions were wrong or were unable to "conform conduct to the requirements of the law." Thus, evaluations of criminal responsibility will require evaluating

1. the possible presence of a mental illness or intellectual disability, and
2. a person's motivation, reasoning, and level of control when committing a criminal act.

Defendants found not guilty by reason of insanity are acquitted. They are generally committed to psychiatric care following their acquittal. There are other situations in which defendants may assert that their mental functioning significantly impacted their crime in ways to lessen their culpability though not to the extent to fully excuse them from it.

Diminished capacity refers to the inability to form intent or lack of specific intent required for a crime (e.g., the premeditation typically required for first-degree murder). Defendants successful in arguing diminished capacity are typically convicted of lesser offenses.

The Assessment

As mentioned earlier, an evaluation of criminal responsibility involves assessment of the presence of mental illness or developmental disabilities and possible links of such problems to the crime. Assessments will include a review of available records including police reports and a detailed interview with the defendant. Evaluators must reconstruct a person's mental status at the time of their offenses by speaking to them and those who may have observed the crime and/or the person's behavior close in time to it. Part of this will be a thorough review of his account of the crime. Given the potential for self-incrimination, informed consent and advisement of rights are extremely important. Psychological testing may be used to support the diagnostic process, though forensic assessment instruments focused on criminal responsibility are not prevalent.

Controversies and Issues

The retrospective nature of evaluation of criminal responsibility poses a significant challenge for evaluators. Mental health professionals are trained to diagnose mental health disorders by collecting data on past history and current symptoms. Current symptoms may actually be irrelevant to criminal responsibility for a prior act though they may add support to the presence of a diagnosis needed to establish the basis for not guilty by reason of insanity defenses. Research has made clear that memories can change over time, even in the absence of overt attempts to dissimulate or provide inaccurate information. Thus, inconsistencies between current reports and those made closer in time to the crime or in official records may need to be reconciled.

There is a misconception among the public that the insanity defense is overused and is an attempt to literally get away with murder. In reality, the defense is rarely used and even more rarely successful. Nevertheless, given the high stakes involved, the potential for malingering may be high in these cases and should be assessed.

Risk Assessment

The Psycholegal Question

The question posed in forensic risk assessment appears fairly straightforward: How dangerous is

this person and what is the likelihood that he or she will reoffend? The ultimate issue a judge or jury will consider in these cases typically focuses on punishment and the level of confinement that punishment should be completed in. Risk assessments may also be completed prior to release from confinement to determine the level of supervision needed in the community. Risk of violence or reoffense is generally believed to result from a combination of *static risk factors* that do not change such as criminal history and *dynamic risk factors* that are malleable over time such as substance use. *Protective factors* such as strong social support may also be considered. Thus, risk assessments are also capable of identifying areas that can be targeted in treatment in which an offender may be court-ordered to participate.

The Assessment

As previously described, risk assessment involves collection of both historical and current information about an offender. A variety of risk assessment tools were developed after it was determined that mental health professionals were unable to make accurate predictions about future risk using only their professional judgment. Although interviewing of offenders and review of records to obtain objective historical information remain important parts of these evaluations, risk assessment tools are now commonly used as well to improve reliability and accuracy. These measures differ in their development and administration, however. Structured professional judgment measures serve as interview guides that assist evaluators in systematically considering risk factors that have been identified in the literature. The risk level posed by an offender is still determined by the evaluator's overall impression of him or her. Actuarial measures also consider identified risk factors, though in these measures, risk factors have been statistically associated with reoffending and allow for comparison between the offender being assessed and a normative sample. In other words, the measure can provide a more specific and sometimes a quantitative risk level.

Controversies and Issues

Risk assessments are unique forms of forensic assessment in that they neither attempt to describe

current or past functioning but predict an event that *may* occur in the future. There is no current assessment approach or technique that can do this with 100% certainty (and likely never will be). Science can estimate the risk of reoffense and error rate of a specific technique, but determining what actions to take at different risk levels and how much uncertainty to allow in the accuracy of a specific assessment must be subjectively determined by the trier of fact. As a result, evaluators are urged to report the limitations of their findings in their reports.

Civil Commitment of Sexual Offenders

The Psycholegal Question

In cases of civil commitment of sexual offenders, the question evaluators must answer again centers on dangerousness, specifically an individual's risk of sexual reoffense. Of note, the ultimate issue in these cases is not decided at a criminal trial but at a civil hearing after the offender has already served a sentence for his or her crime. Although specific statutes vary across jurisdictions, these are often referred to as *sexually violent predator* laws in the United States and require (a) a history of sexual offense, (b) a diagnosable mental health problem or condition, and (c) a high level of risk of reoffense. Forensic mental health evaluators are typically asked to address the latter requirements by diagnosing a type of mental disorder marked by abnormal sexual interests or behavior known as a *paraphilia* or other mental health disorder that can be causally linked to deviant sexual behavior and by offering an assessment of an individual offender's current level of risk of future offending. Individuals who are at high risk may be confined in treatment facilities or ordered to submit to outpatient treatment and supervision indefinitely.

The Assessment

Assessment of risk for the purpose of civil commitment proceedings is much the same as that described earlier with the addition that a diagnosis is often required by statute. Of all the types of forensic assessments reviewed in this entry, civil commitment of sexual offenders is the most recently developed, and assessments may show

variability until best practices evolve. However, risk assessment measures specific to sexual offending are available and are generally used.

Controversies and Issues

The issues related to the prediction of future behavior described previously are applicable to this form of evaluation as well and perhaps amplified given the fact that offenders have already served time for their crimes. Prioritization on community safety often results in support for these laws, while some point out that they infringe upon the civil liberties of offenders by submitting them to a legal form of double jeopardy that is particularly unfair given limitations in the accuracy of risk assessment and effectiveness of sexual offender treatment. Evaluators' attempts to address this by clearly presenting quantitative predictions of risk from actuarial instruments when available may not address this issue, as research has found that jurors may find any risk as *significant risk*. As currently written, sexual predator laws may reflect a problematic blurred boundary between the legal and mental health systems.

Juvenile Offenders: Amenability to Treatment and Waiver to Adult Court

The Psycholegal Question

The juvenile justice system's approach to youthful offenders has evolved over its history. While initially established on the premise that the criminal motivation and possible rehabilitation of children and adolescents differed from adults and required specialized attention, Supreme Court cases such as *Kent v. United States* (1966) and *In Re Gault* (1967) determined that juveniles should be afforded many of the same rights as adult defendants. The law typically allows youth of a certain age or accused of certain crimes to be tried and sentenced as adults. For some serious crimes, waiver or transfer to adult court may actually be mandated by the law. In other situations, there is prosecutorial or judicial discretion. The frequency of such cases has varied depending on public sentiment regarding the seriousness of juvenile crime. When discretion is possible, a forensic assessment may be requested to assist decision makers in determining the juvenile's dangerousness and

amenability to reform with treatment in the juvenile justice system. If it believed that the juvenile cannot be safely maintained or rehabilitated within the juvenile justice system, the case may be heard in adult court opening the juvenile up to adult sentences.

The Assessment

Evaluation of amenability to treatment or waiver of juveniles may resemble general mental health assessment more than other types of forensic assessment as key questions are whether the juvenile has an identifiable mental health problem and their specific treatment needs. Identification of treatment needs is not enough, however. Another aspect of these evaluations involves assessment of dangerousness. Thus, assessments will typically involve a review of records, interviews with the juvenile and those who are familiar with him or her, and formal risk assessment.

Controversies and Issues

As mentioned earlier, assessment of risk of violence or reoffense can be enhanced with testing, but concerns about false positives are great. This may be particularly true in the case of juvenile offenders for whom a degree of illegal behavior may reflect normative developmental changes in risk taking and impulsive decision-making. Risk assessment measures used should therefore have been developed and tested with adolescents, though fewer measures are available for this group. Once in the adult system, if mandatory sentences following conviction are seen as at odds with the general juvenile court process of individual sentencing, then the decision to waive a juvenile's case to adult court should be made by the trier of fact with all available information.

Conclusion

Forensic assessments of offenders are used to answer specific questions for the legal system. Although the questions may vary across assessment types, all forensic assessments differ from general mental health assessments in important ways that call for specialized knowledge and

training. Each form of assessment also brings its own unique set of unresolved issues and controversies. Assessments that answer psycholegal questions as accurately as possible and acknowledge any weaknesses or limitations have the best chance of assisting both the legal system and the offenders who find themselves within it.

FORENSIC INTERVIEW

The forensic interview is a key element of any forensic evaluation. This detailed interview is used to gather information and clinical data required to answer a specific psycholegal referral question. The following sections outline the unique characteristics of forensic interviews, including legal contexts, referral questions, and other important considerations (e.g., use of collateral information, bias and judgment error, safety and ethical considerations).

Characteristics of the Forensic Interview

Forensic interviews differ from typical clinical interviews in multiple ways. The scope of the forensic interview and the role of the examiner vary considerably depending on the context and the referral question. Unlike most clinical interviews, which typically emphasize diagnostic assessment and establishing treatment goals, forensic interviews focus on gathering data to answer a specific psycholegal question. The perspective of the person being examined also holds less importance, as the goal of the evaluation is to develop the most accurate impression possible, based on information from *all* relevant sources. A typical clinical interview, on the other hand, usually relies solely on the patient's report of events, experiences, and emotions.

The forensic examiner must also be aware of his or her relationship with the examinee. Although an examinee may decline to participate in a forensic interview, many legal contexts prevent the examinee from limiting the information that is disclosed to other parties. That is, a report may be prepared regardless of whether the examinee participates in the evaluation. Furthermore, while establishing rapport is critical to a successful forensic interview, the potential for negative outcomes for the examinee may limit the extent to which an examiner should encourage a frank disclosure of information. There will also be situations in which an examiner may need to challenge, confront, or probe the examinee in order to resolve real or perceived discrepancies or to clarify ambiguous information.

Forensic interviews are particularly vulnerable to threats to the validity of the information gathered. The results of a forensic examination often impact an examinee's liberty, creating a strong incentive for distortion, fabrications, or withholding relevant information. The examiner must consider the possible motivations of the examinee and other collateral sources, which may increase the likelihood of distortion (whether minimization or exaggeration).

Lastly, the forensic examiner must be cognizant of the pace and setting of forensic interviews. The examiner may have limited time to conduct an interview and may not have the ability to conduct a follow-up interview, as access to correctional settings may be limited and legal proceedings are often time sensitive. Therefore, it is critical that the examiner collect as much relevant information as possible within the time available.

Legal Contexts

The goals of a forensic evaluation differ depending on the legal context and the corresponding psycholegal referral questions. For example, pretrial and trial evaluations assess an individual's competency, decision-making abilities, or mental state at the time of an alleged offense, whereas custodial evaluations typically assess an individual's risk of harm and mental stability in order to inform security and treatment interventions. Lastly, pre- and post-release evaluations assess an individual's risk of reoffending violence or mental health needs following an individual's return to the community.

Pretrial and Trial Evaluations

Both prior to and during legal proceedings, forensic examiners may be asked to evaluate an individual's competency, decision-making abilities, or mental state at the time of an alleged offense. For example, forensic examiners may be asked to assess an individual's competency to waive Miranda rights or make a statement to the police or to assess an accused's competency to stand trial. Other pretrial referral questions include an individual's competency to represent one's self (i.e., to waive the right to counsel), to plead guilty (i.e., to waive the right to trial), to be sentenced, or

even to be executed. With the exception of competence to confess or waive *Miranda* rights, examinations of competency focus on the individual's present mental state and, therefore, require a careful examination of the individual's current mental functioning.

A forensic examiner may also be asked to assess an accused's sanity at the time of the offense. Like an evaluation of competency to waive *Miranda* rights, a mental state evaluation focuses on the individual's psychological functioning at a previous point in time. Hence, the examiner will typically merge interview data with collateral sources (e.g., medical records, witness statements) to determine an individual's mental state at a previous point in time.

Because virtually all pretrial evaluations require an assessment of the person's current mental state, the forensic interview will typically include a review of the examinee's social, psychiatric, medical, and education history. In addition to a clinical interview and gathering collateral information from available records (e.g., police statements, mental health records, criminal history, witness statements), the examiner may also use psychological assessment tools to assess for cognitive impairment, psychiatric symptoms, or exaggeration (i.e., malingering).

Custodial Evaluations

Custodial forensic evaluations can also occur in a variety of criminal justice contexts. Following admission into a correctional facility, clinicians often assess the inmate's intelligence, suicide risk, violence risk, and symptoms of a mental illness. These evaluations typically help gauge whether an imminent risk of harm exists, as well as mental stability for, and appropriateness of available treatment programs (e.g., anger management, substance abuse treatment).

Unlike most pretrial forensic evaluations, custodial evaluations are more akin to general clinical evaluations, with the exception of the setting and the incentive to distort symptoms. The examiner often has little information about the examinee's history and therefore must be prepared for severe symptoms that have not previously been identified. However, evaluations conducted in custodial settings have a greater risk of violence; thus, the

examiner should take precautions to ensure his or her safety during the interview (e.g., adequate physical distance from the examinee with access to the exit, awareness of the facility's safety procedures). Finally, because of the inherently coercive setting, the examiner must be mindful of the potential for deliberate symptom exaggeration or minimization.

Pre- and Postrelease Evaluations

Forensic examiners are often asked to complete pre- or postrelease evaluations in order to inform a judge, parole board, or probation officer about the examinee's risk to the community. The specific focus of these evaluations depends on the referral question, though three overarching questions are most common: general risk of reoffending (e.g., for parole evaluations), specific questions regarding violence risk, and mental health treatment needs. Violence risk assessments may focus on a specific type of risk, such as sexual violence in jurisdictions where involuntary commitment of sex offenders is possible. In evaluations of risk of violence or reoffense, forensic examiners often utilize some form of structured risk assessment instrument in order to evaluate the relevant risk and protective factors. The forensic examiner may also be expected to make recommendations for risk management, such as identifying treatment needs or suggesting interventions that could facilitate community reintegration and reduce risk.

During pre- and postrelease evaluations, the examiner often elicits information about the examinee's criminal history, attitudes toward violence, and plans for the future. Collateral sources may also help identify resources available to the individual in the community (e.g., social support, employment opportunities). Lastly, although examinees are rarely motivated to exaggerate psychiatric symptoms during pre- and postrelease evaluations, assessment tools may aid in the detection of minimization.

Other Considerations

In addition to collecting clinical data from forensic interviews, forensic examiners must also consider several other important factors during the interview and evaluation process that will aid in

objectively answering psycholegal questions. These include the incorporation of collateral information, assessment of false or distorted information, and recognition of potential bias or judgment error. Finally, the examiner must also be aware of safety and ethical considerations that may be unique to the interview's forensic context.

Collateral Information

As noted earlier, forensic interviews are often bolstered by collateral sources in order to corroborate information provided by the examinee. Collateral informants can include those who are, or have been, in frequent contact with the offender (e.g., relatives, friends, employers) or have observed the individual (e.g., victims of or witnesses to the offense). Medical and criminal justice records can also provide useful information. Of course, the availability and utility of collateral information will vary across cases and settings. For example, medical records may not exist and it may be difficult to contact family members or friends. Resolving conflicts between self-report and collateral information can often require the evaluator to determine which source seems most credible. When collateral information is unavailable, the examiner is forced to rely more heavily on self-report and should be appropriately cautious in rendering conclusions.

False or Distorted Information

As mentioned earlier, providing false information during a psychological evaluation, whether due to resistance, embarrassment, or limited trust, is common in forensic interviews. To help compensate for the problems posed by distorted responding, evaluators often rely on psychological tests that explicitly assess defensiveness and/or symptom exaggeration.

Bias and Judgment Error

Another issue that should be considered in forensic interviewing is the potential for bias or judgment errors on the part of the examiner. Forensic evaluators are often provided with information about the examinee and his or her alleged

(or known) criminal history or records of prior psychiatric diagnoses or evaluations. These sources of data, while important, may lead to preconceived beliefs or expectations about the examinee. Hence, the potential for a confirmatory bias, whereby the examiner poses questions intended to confirm these preexisting beliefs about the examinee and may fail to ask questions that do not, can impact the accuracy of the evaluation. To minimize the possibility of bias, it is important that the forensic evaluator identifies these potential threats and explicitly searches for information that could disconfirm expectations.

Safety Considerations

As noted earlier, the potential for aggression in forensic settings often requires safety precautions during the forensic interview. Before starting an interview, the examiner should inquire as to the examinee's current state or the presence of any agitation. Precautions should also be taken in order to ensure both the examiner's and the examinee's safety during the evaluation. For example, the examiner should be aware of the facility's safety procedures and avoid bringing (or permitting access to) items that could be used as a weapon. Seating arrangements should be established that positions the examiner closest to the exit, while maintaining a safe distance from the examinee. Some interview rooms have a panic button or even require that institutional personnel be present during the interview (ideally far enough away to minimize confidentiality concerns). Although not ideal, some form of physical restraints may even be necessary in order to provide adequate security for the examiner. During the interview, the examiner should be alert to indications of aggression (e.g., changes in the examinee's behavior, raised voice or hostile tone). If the examinee becomes agitated or upset, the examiner should attempt to de-escalate the situation and/or discontinue the interview.

Ethical Considerations

There are several resources that help examiners navigate the forensic interview, including the American Psychology–Law Society's *Specialty Guidelines for Forensic Psychologists* and the American

Psychological Association's *Ethical Principles of Psychologists and Code of Conduct*. Two of the most complicated ethical issues that a forensic interviewer must consider are informed consent and confidentiality. The forensic evaluator must recognize that the *client* is not necessarily the individual being interviewed. Rather, the examiner is often retained (or employed) by a third party such as an attorney, judge, or government agency. Therefore, it is imperative that the examiner informs the examinee of the nature of the interview (e.g., procedures, who the examiner works for), risks and potential benefits of participating in the evaluation, and the consequence of declining to participate. Although in many settings an examinee's refusal to participate does not prevent the evaluation from taking place, this disclosure is required for informed consent. Furthermore, while the examinee's right of privacy should be respected, forensic interviews are often conducted in jails or prisons, where privacy is not guaranteed or even possible. Interviews may need to be conducted in open settings, where other people can overhear the evaluation. The examiner may be able to impact these circumstances but often cannot. Lastly, the examiner should explain the limits of confidentiality in the context of the forensic interview, including who will receive copies of the reports and whether other individuals will be informed of information disclosed (e.g., threats of harm to self or others). These disclosures will usually enhance not detract from establishing rapport, as examinees typically appreciate candor and honesty, and are unlikely to expect confidentiality.

Final Thoughts

The forensic interview is a cornerstone of all forensic assessments. Developing the skills necessary for a competent forensic interview is challenging and requires a multifaceted approach to the process. Only with vigilance to the unique characteristics of the forensic interview can the evaluator maximize accuracy and objectivity.

FORENSIC MEASURES FOR ASSESSING OFFENDERS

This entry reviews instruments that mental health clinicians commonly use to assess psychological symptoms, personality traits, behavioral problems, and psycholegal issues relevant to the assessment and management of criminal offenders. The instruments reviewed encompass a variety of formats, including self-report inventories, clinician rating scales, and structured clinical interviews that assess the presence of mental disorders, risk of violence and sexual offending, and response style.

Assessment of Psychiatric Symptoms and Mental Disorders

The high frequency of mental disorders among inmates in the United States is well established. Assessing the presence and nature of psychiatric symptoms often impacts offender management while incarcerated.

Self-Report Inventories

Multiscale self-report inventories have multiple advantages, including group administration, computerized scoring and interpretation, and broad coverage of symptoms and mental disorders. The Minnesota Multiphasic Personality Inventory-2 (MMPI-2), its revised, short-form (MMPI-2-RF), and the Personality Assessment Inventory (PAI) are frequently used in forensic settings. These instruments are intended for use with adults who have at least a fourth- to sixth-grade reading level

and assess a range of symptoms, maladaptive personality traits, and behavioral problems. Although the MMPI-2 has more research support, the PAI may have broader application in correctional settings because it requires a lower reading level and offers *correctional* normative data that can inform judgments of risk of institutional misconduct and treatment needs. Versions of these instruments have also been developed for adolescents (i.e., MMPI-2-A, PAI-A) with item content modified to reflect developmental differences between adolescents and adults.

Screening Measures

Brief screening measures are used to identify those who require a more comprehensive psychiatric evaluation and may be useful when evaluating large numbers of individuals. Typically, screening measures are administered orally and require fewer than 5 min to complete. For example, the Brief Jail Mental Health Screen contains only eight questions assessing current mental health symptoms and treatment history. The Brief Jail Mental Health Screen was developed for use with adults and has demonstrated good predictive accuracy in identifying offenders with a mental disorder, although it may be more accurate for men than for women. A widely used screening tool for youth is the Massachusetts Youth Screening Instrument-Version 2. The Massachusetts Youth Screening Instrument-Version 2 has separate forms for boys and girls and is typically used upon entry to a juvenile justice facility to identify the mental health needs that can (or should) be addressed.

Cognitive Assessment Instruments

Cognitive disorders, including both intellectual disability (ID) and traumatic brain injury, are common in offender populations and can hinder the accuracy of other diagnostic approaches (e.g., self-report inventories). ID is characterized by significant deficits in intelligence and adaptive functioning (i.e., the extent to which an individual can function independently in activities of daily life). Although no measures have been developed specifically for assessment of cognitive functioning in correctional settings, a wide range of cognitive/

neuropsychological instruments can be used for this purpose. However, as these instruments are vulnerable to insufficient effort, cognitive assessment tools should be accompanied by measures of effort to ensure that the individual has performed to the best of his or her abilities. Similarly, no measures of adaptive functioning have been developed for correctional settings although a number of such scales exist, and the assessment of adaptive functioning is further complicated in correctional or forensic settings because offenders have little opportunity to demonstrate adaptive functioning abilities.

Risk Assessment Instruments

Another major focus of mental health assessment in the criminal justice system is violence and recidivism risk. Risk assessments influence both pre- (e.g., sentencing) and post-adjudication issues (e.g., parole eligibility). Research has repeatedly shown poor accuracy rates for risk assessments based on clinical judgment alone; the use of risk assessment instruments can help the clinician structure his or her decision-making, either through the application of a predetermined algorithm to gauge risk level (i.e., an actuarial approach) or identification of risk factors to be considered (i.e., the structured professional judgment [SPJ] approach). Violence risk assessment instruments also differ in the types of risk factors they include. Some include only static risk factors or those that relate to an offender's history or personal characteristics that are stable over time, whereas others include dynamic risk factors or those that may change over time.

SPJ Instruments

The SPJ approach to risk assessment is best exemplified by the Historical-Clinical-Risk Management-20 (now in its third revision; HCR-20^{v3}). Intended for use with adults in correctional or mental health settings, the HCR-20^{v3} contains 20 static and dynamic risk factors for violence grouped into Historical (e.g., history of violence), Clinical (e.g., current mental health symptoms), and Risk Management (e.g., future problems with treatment adherence) categories. Clinicians rate the presence and relevance (for the individual

being evaluated) for each risk factor and then use these ratings to develop a risk formulation, identify scenarios in which violence might occur, and generate risk management strategies. Clinicians also generate three summary risk ratings (Case Prioritization, Serious Physical Harm, and Imminent Violence—each rated as low, moderate, or high) to communicate the individual's violence risk. A large body of research has demonstrated the utility of the HCR-20 with criminal offenders and forensic psychiatric patients. Other SPJ instruments target specific types of violence (e.g., sexual offending) or focus on a wide array of problem behaviors. For example, the Short-Term Assessment of Risk and Treatability contains 20 dynamic items that are used to evaluate risk of multiple problem behaviors, including violence, suicide, self-harm, recidivism, and treatment noncompliance.

Several SPJ instruments have been developed to facilitate the evaluation of risk in youth. For example, the Structured Assessment of Violence Risk in Youth comprises 24 static and dynamic risk factors and, unlike most SPJ instruments, includes six protective factors. Like the HCR-20, clinicians use these ratings to evaluate the youth's overall risk level and identify potential targets for intervention. Similarly, an adolescent version of the Short-Term Assessment of Risk and Treatability is used to assess multiple domains of risk in juveniles.

Meta-analytic studies have consistently supported the predictive accuracy of SPJ tools. However, the reliance on individual case analysis and the need for specialized training often limit the applicability of SPJ approaches in correctional settings, where large numbers of offenders require a prerelease assessment.

Actuarial Risk Assessment Instruments (ARIAs)

ARIAs structure both the identification and weighting of risk factors and generate a probabilistic estimate of violence risk. Most ARIAs rely exclusively on static risk factors, although some include dynamic risk factors and/or assess change over time. One widely used ARIA is the Violence Risk Appraisal Guide (VRAG), and its revision, the VRAG-R. The VRAG was developed for use with adult offenders or forensic psychiatric

patients and contains 12 static risk factors targeting demographic/personal background and health/criminal history variables. Total scores on the VRAG/VRAG-R are grouped in one of nine *bins* that are associated with a probability of future violence. However, the VRAG, like most ARIAs, fails to account for change over time and omits idiosyncratic risk (or protective) factors that could impact an individual's risk.

A widely used ARIA for gauging risk of recidivism is the Level of Service Inventory (LSI). The LSI is based on the Risk-Need-Responsivity model, which provides that risk management strategies are most effective when they are proportionate to the offender's risk level, address the individual's criminogenic needs, and account for characteristics that may impact how the offender responds to treatment. The LSI family of instruments includes a case management version (LS/CMI), a youth version (YLS/CMI), and a screening version. These tools comprise static and dynamic risk factors grouped into eight subcomponents (e.g., Criminal History, Education/Employment). These instruments generate a total score quantifying the offender's overall risk/need level and eight subcomponent scores used to identify risk factors that may be targeted through treatment or supervision. Unlike many ARIAs, the LS/CMI and YLS/CMI encourage clinicians to develop their own estimate of risk based on the combination of their clinical judgment and actuarial data.

Psychopathy Instruments

As part of a risk assessment, clinicians often assess psychopathy, a personality construct characterized by interpersonal (e.g., dishonesty), affective (e.g., callousness), lifestyle (e.g., irresponsibility), and behavioral (e.g., criminality) traits. Research indicates that psychopathy is one of the strongest predictors of violence and general reoffending among adult offenders, although evidence supporting this construct is more mixed in juveniles. The most commonly used psychopathy instruments are those developed by Robert Hare and colleagues: the Psychopathy Checklist-Revised, Screening Version, and Youth Version. Individual Psychopathy Checklist Item scores are summed to yield a total score that reflects the severity of psychopathic traits. Self-report measures of

psychopathy have also been developed, such as the Psychopathic Personality Inventory–Revised. However, given the risk of deliberate distortion, self-report measures are typically only utilized for research.

Sex Offender–Specific Instruments

A number of SPJ and ARAI tools have been designed for the assessment and management of sexual recidivism risk. Adult sex offender–specific SPJ tools include the Sexual Violence Risk-20 and the Risk of Sexual Violence Protocol. Modeled after the HCR-20, these tools guide clinicians through a series of ratings regarding the presence and relevance of static and dynamic risk factors, culminating in a summary rating of the offender’s overall sexual recidivism risk (low, moderate, or high). Although a modest literature has demonstrated strong support for these tools, the existing research is far less robust than for the HCR-20. The Static-99 (and expanded version, Static-2002) is the most commonly used sex offender–specific ARIA. The Static-99/Static-2002 (both of which were revised in 2009; Static-99R/Static-2002R) was developed for the assessment of sexual recidivism risk in adult males and assess static risk factors (with the exception of age). More recently, the Violence Risk Scale–Sexual Offender Version was developed to incorporate dynamic risk factors and assess change over time, while still maintaining the actuarial approach to decision-making. Scores generated by the Violence Risk Scale–Sexual Offender Version (static and dynamic Items) generate both probabilistic and qualitative (e.g., low, moderate–low) risk judgments.

A parallel set of risk assessment tools has been developed for juvenile sex offenders. Among the most widely used are the Juvenile Sex Offender Assessment Protocol–Revised and the Estimate of Risk of Adolescent Sexual Offense Recidivism. The Juvenile Sex Offender Assessment Protocol–Revised contains 28 items that encompass both static and dynamic risk factors and form two static scales (Sexual Drive/Preoccupation; Impulsivity/Antisocial Behavior) and two dynamic scales (Intervention; Community Stability and Adjustment). The Estimate of Risk of Adolescent Sexual Offense Recidivism consists of 25 items divided into five domains: history of sexual assault, sexual

interests and behaviors, psychosocial functioning, family/environment, and treatment. As with the HCR-20, clinicians use their item ratings on the Juvenile Sex Offender Assessment Protocol–Revised and Estimate of Risk of Adolescent Sexual Offense Recidivism to formulate an overall risk estimate. Because there is considerable variability in estimates of their utility, these tools should be used as an adjunct to a thorough, individualized assessment of risk.

Response Style Instruments

An important component of any forensic mental health evaluation is the assessment of response style, including malingering/symptom exaggeration and defensiveness/symptom minimization. Numerous instruments have been designed to aid clinicians in the assessment of malingering and defensiveness, providing critical data about the validity of an offender’s self-reported symptoms or impairment. These instruments are typically divided into those that address cognitive functioning (i.e., cognitive effort) and those that assess validity of reported psychiatric symptoms.

Detecting Exaggerated Cognitive Impairment

Instruments designed to detect feigned or exaggerated cognitive impairment rely on a number of different approaches to detect suboptimal effort. Some measures use the *floor effect*, consisting of overly simple tasks that even those with severe cognitive impairment should complete. For example, the Rey 15-Item Memory Test requires the examinee to reproduce 15 letters, numbers, and shapes arranged in a manner that facilitates memory (e.g., A, B, C, 1, 2, 3). The Rey 15-Item Memory Test and other floor effect measures (e.g., the Dot Counting Test) have limited accuracy in identifying feigned cognitive impairment because examinees often recognize the simplicity of the task. Also, some types of genuine cognitive impairment and/or psychiatric symptoms can affect performance on these tests.

Another strategy used by cognitive effort tests is symptom validity testing (SVT), which compares the examinee’s performance on a forced-choice task to chance performance. The Test of Memory Malingering is a widely used SVT

instrument that involves the presentation of 50 drawings. The examinee is subsequently provided with 50 recognition trials, each containing a previously seen drawing (*target*) and a distractor, and is asked to identify the target. Scores on the Test of Memory Malinger and other SVTs can be compared to chance performance (i.e., less than 50% correct) but can also be compared to normative data based on genuinely impaired individuals. Research has demonstrated strong classification accuracy for the Test of Memory Malinger in individuals with psychosis and traumatic brain injury but a somewhat greater risk of false positives (i.e., incorrect identification of feigning/exaggeration) with adults with dementia or ID.

The Validity Indicator Profile integrates the floor effect and SVT approaches with the performance curve approach. Performance curves analyze an examinee's performance on items of varying difficulty, with the expectation of increasing errors as item difficulty increases. The Validity Indicator Profile includes verbal and nonverbal subtests and classifies an examinee's performance according to effort (high or low) and intention (to perform well or to perform poorly).

There are also cognitive effort tests derived from many commonly used tests. An example of an *embedded* cognitive effort test is the Reliable Digit Span index, a floor effect measure based on an individual's performance on the Wechsler Adult Intelligence Scale, Fourth Edition (WAIS-IV) Digit Span subtest. Digit Span requires the examinee to remember progressively longer strings of numbers and recall them both forward and backward. The Reliable Digit Span is calculated by summing the longest series of digits recalled both forward and backward. Established cut scores generate good predictive accuracy but, like most cognitive effort measures, may misclassify individuals with ID.

Detecting Feigned Psychiatric Symptoms

Measures to detect feigned psychiatric symptoms include both interview-based and self-report scales and can also be embedded within existing symptom inventories or free-standing instruments. Clinicians commonly use the MMPI-2/RF and PAI to detect feigning. Importantly, these measures also permit clinicians to differentiate deliberate symptom exaggeration from random or confused

responding and have been translated into numerous languages, making them useful in cross-cultural evaluations. However, the self-report nature of these instruments limits their use with offenders with severe cognitive impairment or psychosis, as they may not have the literacy, comprehension, or attention span necessary to complete these tests.

Commonly used free-standing measures of symptom exaggeration include the Structured Interview of Reported Symptoms-2 and the Miller Forensic Assessment of Symptoms Test. These instruments use a structured interview format and use multiple strategies to detect feigning (e.g., endorsement of rare symptoms, unusual symptom combinations, discrepancy between reported and observed symptoms). Whereas the Structured Interview of Reported Symptoms-2 utilizes a scoring algorithm to classify response style, the Miller Forensic Assessment of Symptoms Test, a screening tool, uses a total score to identify cases that require more in-depth assessment. Research has found that the Structured Interview of Reported Symptoms-2 has good predictive accuracy in identifying feigned psychosis but questionable utility in identifying feigned mood or anxiety disorders.

Detecting Minimization or Defensiveness

Clinicians frequently use the MMPI-2 and PAI to assess symptom minimization or defensiveness. Both instruments contain scales that assess denial of minor character flaws, exaggerated ability to cope with stress, and minimization of emotional distress. Clinicians also sometimes use free-standing measures of minimization or defensiveness, such as the Paulhus Deception Scales. The Paulhus Deception Scales is a 40-item self-report measure that assesses two types of defensive responding: conscious denial or defensiveness (Impression Management) and unconscious exaggeration of positive attributes (Self-Deceptive Enhancement). Research has found that MMPI-2, PAI, and Paulhus Deception Scales have good classification accuracy in identifying defensive responding.

Trial-Related Abilities

Competence to Stand Trial

The Supreme Court defined competence to stand trial in *Dusky v. United States* (1960),

holding that a criminal defendant must have “sufficient present ability to consult with his attorney with a reasonable degree of rational understanding and a rational as well as factual understanding of the proceedings against him” (p. 402). A handful of instruments have been developed to assist clinicians in evaluating these abilities.

The MacArthur Competence Assessment Tool–Criminal Adjudication (MacCAT-CA) is a semi-structured interview intended for use with adult offenders. Items on the MacCAT-CA are divided into three groups: (1) *Understanding* Items, which assess factual understanding; (2) *Appreciation* Items, which assess rational understanding; and (3) *Reasoning* Items, which assess ability to assist counsel. Understanding and Reasoning Items contain vignettes related to a hypothetical case, whereas Appreciation Items relate to the examinee’s own criminal case. The MacCAT-CA generates numerical scores for each subscale but does not generate an overall index of competence or a determination of competency.

Like the MacCAT-CA, the Evaluation of Competency to Stand Trial–Revised is designed to assist clinicians in assessing competence-related abilities in adult offenders. Evaluation of Competency to Stand Trial–Revised Items are divided into three scales that assess the three primary competence-related abilities and a fourth scale designed to assess response style (Atypical Presentation). Unlike the MacCAT-CA, Evaluation of Competency to Stand Trial–Revised items do not use vignettes but rather assess an offender’s legal understanding and ability to consult with counsel in his or her own case. Items also assess psychotic thought processes that may impact an offender’s rational understanding and ability to consult with counsel. Item scores are summed to generate three scale scores, and cut scores are used to classify the offender’s level of impairment.

Competence to Waive Miranda Rights

Another issue that arises in forensic evaluations where a defendant has made a confession is the capacity to understand Miranda rights. In *Miranda v. Arizona* (1966), the Supreme Court has ruled that a criminal defendant must understand his or her right to silence, utterances can be used against him or her, and the defendant has the right to an

attorney. The most widely used scales to assess these rights were developed by Tom Grisso in the 1970s and recently revised. Like many forensic assessment instruments, Grisso’s Instruments for Assessing Understanding and Appreciation of Miranda Rights Scales are used to inform, but cannot definitively determine an individual’s capacity, and are vulnerable to deliberate distortion or exaggeration.

Criminal Responsibility

In many jurisdictions, the defense of not guilty by reason of insanity is available. This defense is defined differently across jurisdictions; but generally, a defendant raising it must establish that he or she did not understand the wrongfulness of or could not control his or her behavior because of a mental disorder. The Rogers Criminal Responsibility Assessment Scales was specifically designed to assist clinicians in these evaluations and comprises 25 scales that assess factors relevant to the not guilty by reason of insanity defense. Clinician ratings on these scales generate six summary ratings: potential malingering, presence of cognitive impairment, presence of a major mental disorder, loss of cognitive control, loss of behavioral control, and judgment of whether loss of cognitive/behavioral control resulted from an organic condition or mental disorder. The psycholegal criteria ratings are then entered into a decision tree that generates a finding regarding the offender’s mental state at the time of offense (i.e., insane, sane, or no opinion). The Rogers Criminal Responsibility Assessment Scales has displayed good interrater reliability and concordance with not guilty by reason of insanity court verdicts in research; however, the research base supporting this instrument is very limited. Moreover, this tool has been criticized for failing to provide objective criteria to guide clinician ratings and is more useful in helping to organize an assessment of relevant information rather than providing a quantitative assessment of a defendant’s mental state.

Final Thoughts

Although numerous psychological tests are used with criminal offenders, the importance of the clinical issues involved in these evaluations requires reliable, well-validated instruments.

In addition, consideration of cultural differences and educational background, which can impact the accuracy of these measures, is paramount.

FORENSIC PSYCHOLOGY, RESEARCH METHODS IN

Forensic psychology, broadly defined, is the application of psychology to the legal system and questions of law. This can take many forms, such as the assessment of individuals to resolve issues regarding competency to stand trial or criminal responsibility, treatment of individuals in correctional institutions or mandated to community supervision, and the use of psychological research in the courtroom to educate jurors on issues such as the accuracy of eyewitness testimony. Forensic psychologists also apply psychological knowledge to issues pertinent to those working for the justice system, such as police officers exposed to trauma or attorneys seeking help selecting jurors. Forensic psychology research applies the scientific principles of experimentation to answer questions related to police and judicial practices, offender treatment and rehabilitation, and many other intersections of psychology and the law to ensure fair and just treatment across the legal spectrum. Many approaches, methods, and techniques of research are found within the area of forensic psychology. This entry outlines the importance of forensic psychology research, common methods and approaches to research within forensic psychology (including examples), and important considerations when beginning forensic psychology research.

Importance of Forensic Psychology Research

With increasing frequency, psychological constructs, assessments, and research findings are presented within courts of law as evidence via expert witness testimony, so it is important that the process with which these constructs, assessments, and other findings are established is completed with scientific rigor. Calls for *stronger* research (e.g., use of creative and multiple methodologies, replications, greater integration of theory, more interdisciplinary collaboration) have been made in the field. Forensic psychology research is utilized in courts, referenced by policy makers, and implemented in a wide variety of contexts, so findings from research in this area can

have tremendous consequences for current and future legal defendants, inmates, civil matters, policies, laws, and regulations.

Because of the intersection of psychology and the law in forensic psychology, research in this area needs to be robust and thorough enough to be presented as evidence. All evidence presented in court needs to meet the standard of admissibility (i.e., the *Daubert* standard). This legal standard is based upon the rulings of various U.S. Supreme Court cases for determining the admissibility of expert testimony. To be admissible under *Daubert*, the theory or technique in question must (a) have been tested, (b) been subjected to peer review and publication, (c) have a known or potential error rate, (d) have and maintain standards controlling its operation, and (e) have general acceptance within the relevant scientific community. Every theory, method, technique, and assessment introduced as evidence must meet these *Daubert* criteria. When beginning any project, researchers should keep in mind that *any* research in forensic psychology may someday be cited in a court of law and thus should design, conduct, and report on their findings accordingly.

Methods and Approaches

Depending on the particular area of interest in forensic psychology, there are multiple methods for answering the formed research question. Approaches can be divided into quantitative, or qualitative, or a combination of the two. The approaches included in this entry are a small sample of the multitude of research approaches available. More specific methods may exist for particular areas (i.e., eyewitnesses, deception), and researchers are advised to review relevant literature to determine whether an anticipated method is appropriate.

For Research Questions Asking “What Is . . . ?”

To answer research questions related to the description and definition of a construct (an abstract or theoretical idea used to explain a concept of interest), quantitative approaches are used. These approaches can include the use of surveys and rating scales, archival and secondary data collection, and experiments to better understand a

construct or to determine what relationships, if any, exist between constructs.

Surveys and Rating Scales

Survey research is the most commonly used data collection method in forensic psychology. Surveys involve the distribution of a compiled set of questions to participants from the population of interest. The questions can be open- or closed-ended and may cover a wide variety of topics depending on the construct of interest. Surveys can be quickly completed by many participants at one time. Responses are self-reported, meaning participants answer the survey questions themselves, thus making surveys an appealing option for researchers when time and resources are limited. For example, a researcher may use surveys to seek responses from a group of waiting prospective jurors on their perspectives of the use of DNA evidence in a trial.

A rating scale is similar to a survey in the sense that it is a compiled set of questions; however, rating scales include questions that participants answer regarding others. For example, prison officials may be interested to know what impact administrative segregation may have on an inmate's behavior. Correctional officers could be asked to complete rating scales of various inmate behaviors at various time points following an inmate's placement in the segregation unit. The findings can be compiled to determine the frequency of particular behavioral occurrences at each of the measured time points.

Both surveys and rating scales can be used to measure a construct over time (i.e., longitudinal research), and often, they are used for the validation and norming of instruments. Validation and norming includes determining if an instrument measures what it is intended to measure and that the same interpretation of scores is possible with individuals of various races, genders, and ages. This validation and norming is essential for an instrument to meet scientific standards.

Archival and Secondary Data Collection

Researchers do not always have to collect data from a new set of participants to answer a research question. A review of data that already exist can yield fruitful information as well. Many

government agencies maintain annual data on a variety of topics. For example, through the U.S. Bureau of Justice Statistics, a variety of crime and victimization data are available (e.g., hate crime data from the National Crime Victimization Survey). Much of the data is publicly available and can be used for research. Data also can be extracted and utilized from a previous research project; this is known as *secondary data analysis*. For example, a researcher may be interested in whether offenders' scores on a common criminal risk assessment measure change over time. The researcher could review publicly available data (e.g., gathered by a community supervision agencies of parolees for the last 15 years) to compare scores on the measure across time and subsequent criminal outcomes to determine whether there was a change in scores across the time frame and whether it is predictive of crime.

Archival and secondary data collection are advantageous because fewer resources need to be allocated for obtaining information (i.e., data); however, sifting through already compiled data can still be resource intensive. A data set may not be in an easily managed format. An additional drawback is that no new data can be added to the set; therefore, researchers are restricted to the information in the data file. Many data sets from previous researchers or government agencies are available for public access (e.g., National Archive of Criminal Justice Data), and researchers are urged to make their data publicly available to encourage study replication (i.e., the repeating of a previous study with a new sample to determine if the findings are reproducible), as replication strengthens the validity of research findings.

Experiments

Experiments are designed to determine causal effects—in other words, to determine if manipulating one variable significantly affects another variable. These studies also include quasi-experimental studies, whereby there is no true random assignment of participants to study conditions. Experimental studies can be simple or complex, depending on what is being manipulated, and can occur within or outside of a research laboratory. Types of experiments include pretest–posttest designs and randomized controlled trials.

A pretest–posttest design measures a construct before and after the manipulation of a variable (e.g., participation in a treatment program). For example, a researcher is interested in levels of emotional distress and criminal risk for persons in a treatment program designed to reduce criminal behavior. Participants complete measures of distress and criminal risk before (pretest) and after (posttest) the treatment. Scores on these measures are then compared across these two time points to determine impacts of the treatment on the assessed outcomes.

A randomized controlled trial is similar in that there is measurement before and after a manipulation; however, participants are randomly assigned to groups, and one group serves as a control group and does not receive any manipulation or receives an alternative manipulation. For example, an agency considering adoption of a treatment program for use with its probationers convicted of a drug-related offense may contact a researcher to determine the effectiveness of this program on a subset of its probationers. The researcher randomly assigns probationers from the subset to participate in the treatment program or a no-treatment comparison group (treatment as usual), or an alternate treatment program, measuring the substance use of both groups. One group (the experimental group) participates in the targeted program, and then both groups' substance use is measured again. Substance use of both groups is compared to determine whether those who participated in the targeted treatment program demonstrate significant reductions in their substance use compared to those who were not in the target program.

For Research Questions

Asking “How (or Why) Does . . . ?”

Qualitative approaches are often used to answer the question of how or why a construct or phenomenon exists. These approaches allow for the development of theories and models and to uncover possible causal mechanisms between relationships discovered with quantitative methods.

Interviews and Focus Groups

Common approaches include the use of interviews (one-on-one discussion of a particular topic with a participant) and focus groups (a discussion of a topic led by a moderator and multiple

participants). These approaches can include a set of predetermined questions used to guide the discussions, or the discussions can be unstructured. The responses from participants are recorded and analyzed for common themes of the language related to the construct or phenomenon of interest.

For example, previous research determined that inmates did not access available mental health services as anticipated in a local county jail. Several focus groups over the course of 1 month were held at the jail, with the discussion led by a trained research assistant. Discussion topics included level of awareness with the available services, reasons for avoiding access of services, and beliefs about the quality of the provided services. The inmate responses were compared, and commonalities in language were compiled to offer a variety of reasons for the inmate failure to access the resources.

Case Studies

Case studies are an in-depth analysis of a single or small number of participants. The participants can include an agency (e.g., a community supervision agency), a group of people (e.g., persons in a substance abuse or mental health court), or a single person (e.g., convicted serial killer). A case study may involve review of the participant records (e.g., investigative reports, personal documents, behavioral records) to extract material related to the area of interest and/or interviews with members of (or related to) the participant. For example, a researcher interested in experiences of police officers undergoing fitness-for-duty evaluations may conduct interviews with a small sample of police recruits who recently completed such evaluations to better understand the concerns that officers have when participating in these types of evaluations.

Important Considerations

The selection of research method depends on the level of both internal validity (ability to determine causality of findings) and external validity (ability to generalize findings to other people, places, and situations) desired as well as available resources. One of the primary research challenges in forensic psychology can be differences in definitions of legal concepts from state to state and country to

country. Thus, it is important for researchers to be familiar with the relevant laws and concepts related to the area of study.

FRAUD

Fraud is a violation of trust. At its core, it is a human act intended to deceive another person in such a way that the victim suffers a loss and the perpetrator makes an unlawful gain. Although fraud can be considered theft, such theft is not by force. Importantly, there is no robbery at gun-point, no direct threat of harm or injury to the victim, or even any use of physical force. Rather,

the perpetrator relies on lies, misrepresentation, or betraying the trust of another in order to gain money or something else he or she considers to be of value. This entry begins by reviewing a few theories of crime as they relate to fraud; it then discusses the status of the development of criminological profiles and ends with a discussion of the prevalence and risk associated with fraud, especially among businesses and organizations.

Theories

Many psychologists and criminologists believe that fraud, like any other crime, can best be explained by three factors: a supply of motivated offenders, the availability of suitable targets, and the absence of capable guardians. This section introduces two other theories that also invoke a triad: the A-B-C theory and the fraud triangle.

A-B-C Theory

In 2013, as part of the emerging discipline of behavioral forensics, which explores human motivations for crime, Sridhar Ramamoorti and colleagues proposed the A-B-C taxonomy or the *bad apple, bad bushel, and bad crop* theory. The A-B-C theory posits that when considering fraud, one should employ a multilevel analysis, moving from the individual to a colluding group to an entire culture or environmental factor. In addition, different units of analysis corresponding to the level of fraud perpetration—that is, apple (individual), bushel (group), and crop (culture)—may be called for. Under the A-B-C typology, an individual acting alone would be characterized as a bad apple. When there are accomplices and thus collusion is involved, it is a case of a bad bushel. When an organization's leaders engage in corrupt behavior, however, and the whole culture is toxic, it is considered a bad crop. The bad crop syndrome can result in a normalization of deviance and can even afflict an entire industry—for example, the 2012 London Interbank Offered Rate rigging scandal, whereby major European banks reportedly manipulated interest rates.

Fraud Triangle

The fraud triangle, created by Donald Cressey, includes three vertices: opportunity, pressure/incentive, and rationalization. Cressey notes that none of these elements alone would be sufficient to

result in fraud; instead, all the three elements must be present. Using embezzlement as an example, there must be (a) an opportunity for a financial trust violation, (b) a nonsharable problem (i.e., a problem that one does not want to disclose to another such as drug use or gambling addiction), and (c) a set of rationalizations that define the behavior as appropriate in a given situation (e.g., “I’m just borrowing the money; I’ll pay it back later”; “everyone else is doing it, so why can’t I?”).

The concept of “the dark triad of human personalities”—namely, narcissists, psychopaths, and Machiavellians—has been utilized to challenge the fraud triangle. For those with little or no conscience and devoid of empathy (so-called dark triad personalities), only the lack of opportunity prevents them from lying, making false representations, and emotionally manipulating people to commit fraud. In other words, if the opportunity exists, regardless of the other vertices of the triangle, these personality types are likely to perpetrate fraud.

Criminological Profiles

Theory and research on the psychology of fraud offenders has historically been underdeveloped. However, at least two types of such offenders have been suggested in the literature: the accidental or situational fraudsters and predators. These have also been referred to as the *benign bad apple* and the *malignant bad apple*, respectively. Some researchers have urged that additional research be conducted to better define accidental fraudsters and predators and to develop meaningful criminological profiles. Examining theory from disciplines such as psychology, psychiatry, sociology, anthropology, and criminology can aid efforts to develop criminological profiles in the context of fraud as well as to understand and prevent fraud. The subfield focusing on these issues has been referred to as *behavioral forensics*.

Prevalence and Risk

For almost 20 years, the Association of Certified Fraud Examiners has conducted a global, nonscientific survey of Certified Fraud Examiners concerning the incidence, types, costs, and other characteristics of occupational fraud and abuse every 2 years. Occupational frauds are those in which an employee, manager, officer, or owner of

an organization commits fraud to the detriment of that organization. The three major types of occupational frauds depicted are corruption, asset misappropriation, and fraudulent statements. Findings regarding the characteristics of offenders, length of fraud, type of fraud, source or root cause of fraud, how the fraud was detected, the demographics of perpetrators, and the size of businesses who were victimized are reported. The Association of Certified Fraud Examiners' 2018 *Report to the Nations* estimated that organizations lose 5% of their

revenues to fraud annually. Similarly, the University of Portsmouth's Centre for Counter Fraud Studies in its report *The Financial Cost of Fraud 2018* estimates that globally, as of July 2018, the cost of fraud is £3.24 trillion (US\$4.2 trillion).

The Association of Certified Fraud Examiners also pioneered and popularized *The Fraud Tree: Occupational Fraud and Abuse Classification System* as shown in Figure 1. The Fraud Tree has three major branches, namely financial statement fraud, asset misappropriation, and corruption,

Figure 1 The Fraud Tree

Source: Association of Certified Fraud Examiners (2018), Austin, TX. Reproduced with permission.

along with several examples of each. Of course, it is possible for all the three categories of occupational fraud, which have distinct characteristics and schemes associated with them, to be occurring simultaneously at the same organization.

In September 2016, the Committee of Sponsoring Organizations of the Treadway Commission released a *Fraud Risk Management Guide*. The guide laid out five principles as best practices for businesses and organizations to assess and manage their fraud risk: fraud risk governance (e.g., through policies), fraud risk assessment, fraud prevention activity, fraud investigation and corrective action, and fraud risk management evaluation and monitoring activities.

FROTTEURISM

Frotteurism is considered a sexual disorder that involves rubbing against or touching a nonconsenting individual for the purpose of sexual arousal or, on occasion, orgasm. Most individuals described or diagnosed as frotteurs tend to rub up against unsuspecting victims in crowded public places, such as public transit or shops, and leave the scene quickly after a very brief encounter. In most jurisdictions, such individuals if apprehended face legal charges (e.g., sexual assault) and sanctions for such behavior, although the penalties for frotteuristic activity, even repeated frequently, tend to be minimal. Frotteurism is often described as a *nuisance* or *minor* sexual offense or paraphilia (i.e., psychosexual disorder). Legally, frotteurs are likely to be viewed as fit to stand trial, although, if convicted, they are unlikely to serve lengthy custodial sentences. It is worth noting here that many victims of frotteurs appear to reject the common view that few long-term or serious consequences result from such unwanted touching—a fear of public spaces, a loss of trust in others, and a sense of personal violation are just some of the effects reported by victims.

A number of writers have pointed out that there have been few accounts of frotteurism in the clinical literature. A. P. Patra and colleagues viewed the typical frotteuristic act as involving a young male perpetrator and a female victim, but they cited little credible support for such an assertion. There appear to be no published accounts involving female frotteurs, as noted by Richard B. Krueger and Meg S. Kaplan, but there may well be some women who employ such behavior. The lack of clinical information might account for the relatively recent addition of frotteurism to the

American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders (DSM)* as well as problems concerning prevalence estimate and suggested treatments. This entry reviews the current understanding of frotteurism and discusses several remaining issues.

Understanding Frotteurism

Richard von Krafft-Ebing (1886/1935) was likely the first clinician to document what he termed *frotteurism* or *frottage*, although confusion can arise since it is also a term used now to refer to consenting, nonpenetrative sexual activity to say nothing of the long-standing technique involving rubbing or smudging used by some artists or illustrators. Krafft-Ebing described three cases of frottage, which he understood to be a variety of exhibitionism, at the same time acknowledging that the limited number of cases known until the late 19th century precluded any firm conclusions. While all features of exhibitionism may not be fully understood at present, rubbing against someone does not appear to be in the repertoire of many exhibitionists, so Krafft-Ebing's classification of the disorder is rather questionable.

The American Psychiatric Association is regarded typically as the primary source of information about frotteurism, despite its relatively recent inclusion of the sexual problem in its diagnostic manual, the *DSM*. To obtain a diagnosis of frotteurism, or frotteuristic disorder according to the fifth edition of the *DSM*, an individual must engage in nonconsensual rubbing for sexual gratification usually in a public place over a period of six months with at least three victims. Recurrent, intense sexually arousing fantasies or sexual urges involving rubbing against a nonconsenting person are said to accompany the disorder. The fantasies, sexual urges, or behaviors cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.

The necessity of rubbing, whether public or private, raises the question of the relationship of frotteurism to another similar albeit more obscure notion, namely *toucherism*. Toucherists derive sexual arousal from exclusive use of the hands as opposed to the use of other parts of the body (e.g., groin area). This term is used interchangeably with frotteurism by some clinicians.

Toucherism might be best understood as a variant or subtype of frotteurism.

The origin of frotteurism may well be the result of a chance encounter around the onset of puberty where rubbing in public produces pleasurable sexual sensations and fantasies. Such sensations and fantasies might then be enhanced through more contacts and/or masturbatory sessions to the point where the behavior becomes a very powerful and fulfilling aspect of an individual's sexual identity and repertoire. This learning-based understanding of the development of frotteurism, however, is speculative at this point. Perhaps one component of an expanded learning-based understanding might include certain cultural components. Cultural beliefs or norms supportive of male dominance and control of women, for example, might produce more unwanted public touching of women by men. This appears to be the case in countries such as Japan, where train cars offering sexual segregation have been introduced on some rail services in order to avoid unwanted groping and touching.

In an attempt to understand frotteurism, it might be useful to expand this view of culture and learning, or learning within a cultural context, a little further. Based on James Horley's forensic-clinical work with offenders diagnosed as frotteurs, frotteurs might be best viewed as timid or unassertive rapists, individuals with the likelihood of committing a more serious sexual assault given the right set of circumstances (e.g., sufficient doses of alcohol, a very docile victim). Such an observation came from penile plethysmographic assessments—whereby penile blood flow in response to a variety of sexual scenarios can be viewed, recorded, and analyzed via computer—of men described as frotteurs. Horley's results showed that these individuals were more sensitive to non-violent or less violent material than men convicted of rape, but they did become aroused to coercive sexual stories. Although such a position has not been supported by substantial follow-up research or replication, coupled with a psychosocial theory of general sexual functioning it might provide an explanation of how some individuals develop a proclivity for anomalous sexual fantasies and activities. Krueger and Kaplan speculated that offense severity progression is typical with frotteurism (i.e., physical and/or psychological harm

to their victims increases with subsequent offenses), and this might be due to more confidence and mastery in line with an understanding of frotteurism as an interest, however, transitory, in less violent (i.e., violence minus the blood, extreme pain, and/or death) sexual coercion.

The limited clinical evidence and empirical work concerning frotteurism confuses more than clarifies. There appear to be three general features of frotteurism: Frotteurs have a large number of victims, they are often not arrested, and they are unlikely to serve long sentences. However, such features speak only to criminological or sociolegal characteristics and not to the nature of any hypothesized, underlying disorder. Thus, frotteurism is far from a well-understood disorder.

Unresolved Issues

A number of serious questions about frotteurism remain. Three of the main issues—the prevalence of the disorder, the best treatment approach, and a satisfying theoretical account of the disorder (if, in fact, there is a disease entity or a real and distinct disorder at play here)—require some attention here.

The question regarding the prevalence of frotteurism is a nagging one. Typically, the disorder has been regarded as rare or at least not very common. Some researchers and clinicians, however, argue otherwise. Frotteurism has been presented as a common problem among males in the United States, although the evidence is based on unverified self-reports provided by self-referred sexual offenders who were not incarcerated. Such individuals, during attempts to seek treatment and avoid arrest, may underreport serious sexually anomalous behavior and overreport nuisance or less severe activities. In 2014, R. Scott Johnson and colleagues conducted a review of prevalence studies but found few studies. The few studies that are available typically have small sample sizes and do not include *DSM* criteria for frotteuristic disorder. Rates of frotteurism vary from less than 1–35% of nonclinical male respondents. These prevalence findings point to important problems, methodological, and, otherwise, without answering the question of problem prevalence.

The issue of treatment efficacy of frotteurism is murky in a similar fashion. There appear to be few

if any suitable studies concerning the treatment of frotteurs in the treatment literature. While the use of certain psychiatric medications has been endorsed by some clinicians, very much consistent with the American Psychiatric Association's recommendation, there have been no published research work to support such an approach, and if a learning-based understanding of frotteurism is correct, pharmacotherapy could be understood as merely addressing and possibly just masking the symptoms or expression of the problem rather than getting at the roots of the issue. It appears to be the case that despite a number of treatment suggestions such as various unique individual psychotherapeutic techniques consistent with personal construct theory that Horley has employed over the years, researchers cannot say with any assurance that any treatment is known to be effective.

With regard to a theoretical account or explanation of frotteurism, Kurt Freund, a famous Czech sexologist who relocated to Canada, provided one attempt: courtship disorder. For Freund, frotteurism and all sexual disorders stem from a disturbance of proper courtship behavior that is largely a biologically based disruption of normal sexual desires that produces a wide range of sexual deviance. The origin and exact nature of the disturbance was not specified by Freund, but a number of researchers and clinicians, especially those who adhered to an evolutionary psychological perspective, have promoted courtship disorder as one possible explanation of sexual deviance.

As one alternative theoretical possibility, personal construct theory—a theory that focuses on choice and meaning of particular acts that contribute over time to a characteristic means of interpreting and anticipating events—has been suggested by some researchers, including Horley, as a means of explaining sexual anomalous behavior. In the case of personal construct theory, a learning-based view of the acquisition of a sexual problem like frotteurism is not discarded or ignored; the basis of the sexually anomalous behavior is not the learned behavior per se, but rather, the acquired system of constructs that support and promote the set of behaviors involved in the sexually offensive acts. However, no substantial and compelling evidence to support courtship disorder, learning theory, personal construct

theory, or any other theoretical offering exists at this point.

The exact nature of frotteurism appears to be very open. Although it may appear advisable that real frotteurism be distinguished from feigned frotteurism, what does real frotteurism refer to? One might accept that there are some people, particularly men, who would obtain primary or even exclusive sexual satisfaction from forced and unwanted public caressing or rubbing against unsuspecting women or men, but viewing them as mentally disordered may excuse what can be construed more simply as offensive and unacceptable behavior. One might also ask whether they are engaging in less serious sexual offenses not because of a lack of interest in more serious offenses but because of a temporary or long-term lack of courage. These questions and many others remain unanswered.

G

GENDER AND CRIME

Gender has become one of the most reliable predictors of crime, especially violent crime. Governmental, crime victim, public, private, and self-reporting data sources are consistent in indicating adult males commit more crimes and are more likely to repeat their crimes than their adult female counterparts. Even with juvenile data denoting marked increases in girls committing more serious violent crimes, the overwhelming prevalence of male's criminal involvement continues. This entry begins by reviewing statistical data regarding crime and gender and then examines theories related to criminality among genders as well as the role that genes may play in criminality. The entry concludes with a brief look at gender in the criminal justice system.

Gender and Crime Data

In 2014, the U.S. Federal Bureau of Investigation published its *Uniform Crime Report* comprising data submitted to the Federal Bureau of Investigation from more than 18,000 law enforcement agencies nationwide. Analysis of these data indicates that males committed 6,021,910 crimes, a reduction of 14.6% since 2010. Females during the same period committed 2,202,349 crimes, a decline of 8.5% since 2010. For the category of murder and nonnegligent manslaughter, males committed 6,665 offenses, a reduction of 6.6% since 2010. Females committed 895 crimes, an

increase of 2.2% since 2010. In every criminal category, males committed significantly more criminal offenses than did females during the same period. The exception to these findings is data indicating that females commit more crimes of prostitution and commercialized vice than their male counterparts.

The Office of Juvenile Justice and Delinquency Prevention, 2010–2012, indicated that female juveniles commit higher rates of forcible rape, aggravated assault, larceny-theft, simple assaults, weapons possession, prostitution and commercialized sex, sex offenses (not including forcible rape and prostitution), possession of alcohol by minors, disorderly conduct, offenses against the family and children, public drunkenness, and all other offenses (except traffic) than do males. However, female juvenile offenders account for only 14% of offenders in residential placement. Their male juvenile counterparts account for 83% of offenders in residential placement.

Gender and Criminality Theories

Most theories—including behavioral, biological, biosocial, cognitive, conflict, criminal justice, criminology, cultural transmission, culture of poverty, deterrence and rational choice, differential association, genetics and evolution, labeling, psychodynamic, psychological, psychosocial, routine activities, self-control, social construction, social control, social disorganization, social learning, social strain, structural functionalism, and symbolic interaction theories—focus on crimes

committed by males. However, such theories fail to consider that gender disparity may account for a correlate of crime. Much of the criminality research, however, has not yet identified specific key causations for criminality, especially for women. This entry reviews a few theories that have attempted to address female criminality.

Masculinity Theory and Marginalization Theory

In the past, it had been assumed that women's lesser roles in criminality were either a result of their biology or sexuality. For decades, masculinity theory has posited that women who engage in behaviors signifying masculinity, such as crime and violence, are attempting to compensate for a lack of maleness. New research findings, though, indicate that female crimes result from marginalization, discrimination in family and workplace environments, and/or women's increasingly complex lifestyles as the family's primary provider. Thus, identifying a woman's susceptibility to criminal activity would require considering the personal structures, struggles, oppression, and life experiences she has lived through. Other relevant theories related to female criminality include opportunity theory and marginalization theory, with marginalization theory being considered by many researchers to be the most relevant and significant for analyzing causes of female criminality.

Strain Theory and General Strain Theory

Both male and female offenders are susceptible to Robert Merton's strain theory and Robert Agnew's general strain theory. These theories take into consideration the pressures placed upon individuals who are socially bound to a life of poverty and to whom a legitimate path to success is inaccessible.

Merton's strain theory was based on the principles that all Americans are equal regardless of class, gender, or ethnicity and encouraged to pursue success—albeit success in this theory was measured by the accumulation of material possessions and financial wealth. Through progression, Merton identified that this measure of success was not attainable by all Americans. Thus, he introduced

anomie, detailing that the imbalance of the societal and cultural goals produces unrealistic goals.

Agnew's general strain theory evolved from Merton's strain theory and recognized the societal and cultural limitations placed on all Americans with regard to attaining wealth and resources. Agnew pointed especially to youth and marginalized groups that have had negative experiences, not solely associated with finances. Agnew also pointed out that these limitations, or strains, were unjust, high in magnitude, associated with low social control, and create pressure on and incentives for those experiencing them to engage in criminality.

Some studies indicate that females' likelihood to offend is more about constraint than strain. After attempting all socially approved means of improving their lives without success, some people may determine that nonlegitimate means or self-created opportunities are the only options available to them. Under this theory, the constraint, or turnaround point, for females is when either they are prosecuted and incarcerated or they determine their place in society has improved to the point that they reevaluate and accept societal norms.

Genes and Gender Criminality

Nineteenth-century criminologist Cesare Lombroso explained that female and male offenders displayed traits from generations past due to phenotypical markers found in DNA that allow the older genes to override newer traits because of shortening or prolonging fetal development. In the 21st century, research into DNA is revealing more about the links between genes and violent crime. Two specific genes, the MAOA gene and a divergent of cadherin 13 (CDH13), have been linked with substance abuse, and substance abuse is associated with violent crime. Studies also show that offenders of both genders who had committed nonviolent crimes lack this specific genetic profile.

It is important to note, however, that neither an individual's genetic makeup nor his or her genetic markers should be proffered as evidence of criminality in criminal trials or used to render verdicts because as of 2018, there are no empirical findings demonstrating that a single or combination of

genes, alone or combined, correlates with violence. Despite the lack of empirical support for genetic causation, some creative defense attorneys have used this information in an attempt to influence sentencing. In a 2006 U.S. court case, a jury rejected the defense attorneys' argument that this new genetic research was to blame for their client's actions. However, in 2009, an Italian jury did rely on genetic research to reduce an offender's sentence. Many researchers insist that in the future, the fields of genetics, biology, neurology, and anatomy will help to explain violence and aggression with regard to both genders, thus furthering understanding of gender and crime.

Criminal Justice System

With regard to the criminal justice system's treatment of offenders, investigations conducted by the U.S. Department of Justice, Federal Bureau of Investigation Civil Rights Division, and various nongovernmental organizations have recognized the existence of disparities between the gender related to socioeconomics, maximum–minimum sentencing relative to drug offenses, and sentencing. Because the criminal justice system in the United States tends to focus its funding on the majority offending group (males), the minority offending group (females) often faces disparity with regard to funding, level of care, and rehabilitative services.

To address such gender disparities as well as to mitigate and reduce crime regardless of gender, criminal justice and social policies must support communities and establish interventions that provide vulnerable populations with realistic and sustainable options for active growth and attainable life goals and subsistence. Moreover, society must dedicate itself to rebuilding and creating communities that care for its citizens and promote social responsibility. Failure to do so could impede the identification of programs that identify causes of criminality and that successfully reduce recidivism rates and incarceration of both genders as well as impact research designed to clarify gender criminality.

GENDER AND IDENTITY IN PRISON

The experience of incarceration can have a tremendous impact on an individual's sense of self, or identity, and this impact varies by gender. Because over 90% of the incarcerated people in the United States and around the world are male, prisons have traditionally been understood to be masculine spaces regardless of whom they confine. When society constructs prisoners as male, the people with other gender identities (i.e., women and transgender people) may be overlooked. In light of the vulnerabilities experienced by incarcerated people who do not identify as male, correctional systems are seeking to make prisons and jails more gender responsive.

The Social Construction of Gender and Identity

Unpacking the complicated meanings of gender and identity is critical to understanding how these constructs are enacted in correctional settings. Identity refers to the narratives that are built by internal and external forces to describe the self. These narratives are not static: While some elements of identity may be constant throughout the life course, many dimensions can and do change over time. Identity is produced by an infinite number of characteristics including, but not limited to, family history, peer group, religious beliefs, nationality, ethnicity, socioeconomic status, education, and criminal justice status.

Gender is one of the myriad identities assigned to and assumed by human beings. Like all elements of identity, gender is a socially constructed category. Gender identity often aligns with biological sex organs, but this is not always the case. The terms *man/men* and *woman/women* categorize people by their sex organs (male or female, respectively) and/or the social and cultural characteristics attributed to these categories. Individuals for whom their biological sex and gender identity align are referred to as *cisgender*. Transgender individuals are those people for whom their gender identity does not align with their biological sex category.

Impact of Incarceration on Identity

The impact of incarceration on identity varies by individual. For some people, incarceration may interrupt their existing sense of self. The experience of being arrested, tried, and confined can be a foreign, unforeseen series of circumstances that is incompatible with an existing identity. This disconnection between how a person sees him- or herself and how others see and treat him or her could result in an identity crisis. For others, incarceration, while unwelcome, may not be incompatible with the identity they have constructed for themselves. Knowing that other people with whom they identify have gone to prison could position the experience of incarceration as an expected outcome of their identity. Under these circumstances, incarceration may actually strengthen elements of an individual's identity or sense of self. Gender identity will impact how an individual understands and experiences prison.

Men, Identity, and Prison

Around the world, over 90% of incarcerated people are men, lending a masculine hue to the prison place. In this way, prison can be understood as a rite of passage for men, which reinforces their masculine identity, especially for individuals who are able to construct some sense of power and control while confined—for example, through gang membership or leadership in education or work placements. However, men may also perceive the prison experience as one that undermines their manhood by stripping them of autonomy and power. For example, while incarcerated in the United States, people lose control about when and where they eat and sleep and what clothes they can wear. They can no longer earn even a minimum wage, so providing financial support to family is not possible. They must follow the orders of the prison security and administrative staff and may be punished, and even abused, by these authority figures. All of these circumstances are extremely emasculating, which can partially explain the high incidence of violence in correctional settings. Men may use violence against other inmates or staff to reassert the masculinity that has been diminished by their

confinement. Men who are perceived as weak in this environment may be assigned traditionally female roles and tasks, related to housekeeping, personal care, and sexual behavior.

Women, Identity, and Prison

For women, incarceration is also an experience that can upset their gender identity. To begin with, as explained earlier, prison is a male space so simply being sent into confinement destabilizes the female self. While women also experience a loss of autonomy and power, this pain may be less acute than that among their male counterparts because power and control may have been largely absent in women's community experiences. In the United States, the majority of female offenders are survivors of interpersonal violence. In fact, the harsh circumstances of poverty, substance use, and sexual and physical assault experienced by these women outside of prison may make life inside feel relatively safe and stable.

Nevertheless, the loss of freedom is painful for all incarcerated people, including women. Particularly pronounced is the pain associated with the inability to care for family, especially children. Women are more likely than men to have been living with their children at the time of their arrest, creating a marked separation upon confinement. Women may seek to reconnect with their roles as mother, sisters, and daughters while incarcerated by organizing themselves into ersatz families comprised of other inmates. Same-sex relationships also reflect women's relational selves and desire to identify as a coupled partner.

Transgender, Identity, and Prison

The gender binary organization of correctional systems makes incarceration particularly problematic for transgender people. In the United States, most systems only have facilities for men and women and assignments are made on the basis of biological sex organs. Transgender men, people who identify as men but have female sex organs, who are assigned to a women's prison may be able to enact their masculine selves with relative safety, given the continuum

of gender identities that are present in women's facilities. However, being categorized as a woman by the corrections administration could still be upsetting and disruptive to the individual's gender identity. Transgender women, people who identify as women but have male sex organs, face tremendous danger when they are placed in a men's prison or jail as their gender identity can be perceived as a weakness. Given these vulnerabilities, transgender women are often placed in segregated solitary housing units, isolating them from human contact and essentially punishing them for the system's inability to protect them. There are some correctional units specifically for transgender women in major metropolitan areas in the United States, but most jurisdictions do not have enough transgender offenders to provide this type of gender-specific housing.

Gender-Responsive Services in Prison

In general, the rehabilitative goals of correctional facilities hinge on facilitating the development of positive, noncriminogenic identities among offenders. Desistence from crime is strongly associated with individuals' ability to write new narratives about their lives that do not involve lawbreaking. In light of the gender-related crises of identity that can be produced by incarceration, correctional services have actively sought to develop more gender-responsive programs that foster favorable outcomes including positive gender identities. Attention to gender demonstrates that providing services to women and transgender people that were originally designed for men places these minority groups at a disadvantage: Programs should be *equivalent* but not the *same*. The goal is to move beyond parity (i.e., sameness) and create equality (i.e., equivalence) for all prisoners. Gender-responsive programming considers the gender-specific needs of men, women, and transgender people.

Gender-Responsive Services for Men

The prosocial masculine identities of provider, father, and husband are associated with desistance

from crime. From that, prison rehabilitation programs for men such as education, job training, fatherhood initiatives, and interpersonal skills and self-awareness, including anger management and violence prevention, can promote positive male identities. The need for incarcerated men to enact masculinities related to power as a form of self-defense presents a challenge for these programs that require an honest self-reflection that could be interpreted as weakness. Programs that center on peer mentoring and support can produce individual and community change by breeding new avenues to respect within the prison. In the United Kingdom, sports programs show promise for building positive alliances around teamwork. Fatherhood programming has also been developed to facilitate visitation and build responsible, family-oriented gender identities.

The critical message from these initiatives is that gender also matters for men. Even though men extract power from their hegemonic masculinities, these roles can also inhibit their potential, especially among offenders who are seeking to move away from lives of crime and violence. Teaching and demonstrating noncriminogenic, nonviolent ways to *be a man* is critical to men's recovery and rehabilitation.

Gender-Responsive Services for Women

Gender-responsive approaches for women suggest an overall framework for working with female offenders and specific ideas for mental health programming. These initiatives seek to capitalize on women's social connectedness and identity as caregivers by encouraging them to care for themselves first and strengthen their sense of self-efficacy. System-wide interventions involve altering how staff speak to women, safeguarding against sexual abuse, and assigning female staff to strip search and bathroom protocols. Behavioral health services focus on treating the high rates of mental illness among this vulnerable population and confronting women's histories of trauma and grief with a range of services from talk therapy to dance. The understanding of women's lives as relational endorses peer support programs and efforts to foster connections with community and family during incarceration and at release, especially between mothers and their children.

Education and job-training skills are also critical to helping incarcerated women build positive narratives about their potential.

Gender-Responsive Services for Transgender People

In addition to services described for men and women, transgender people may require specific medical services related to their gender identities. Many transgender people take hormone medication to allow their physical selves to align with their gender identities. Continued access to this treatment upon incarceration is critical and is legally required for individuals who have been diagnosed with gender identity disorder. For people without this specific diagnosis, and those who want to initiate hormone therapy while incarcerated, access to care may be more difficult. There is also considerable debate about whether or not correctional systems are responsible for providing sex reassignment surgery. Even though incarcerated people have a constitutional right to medical care, the lack of consensus about whether this type of surgery constitutes an elective or medically necessary procedure means that the procedure is not generally covered by correctional health services. In addition to these medical procedures, access to cosmetics, hair products, and gender-appropriate clothing, including undergarments, may also be needed for transgender people to uphold their gendered identity while incarcerated. Failing to provide these services may result in disruptive behaviors, including self-harm, that are detrimental to both institutional and individual outcomes.

GENDERED PATHWAYS

Gendered pathways is a research area that emerged within feminist criminology at the end of the 1980s. This paradigm acknowledges the importance of women's unique experiences that may contribute to their offending behavior. The life histories of women in the criminal justice system are often used to contextualize and understand their initial criminal behavior and recidivism as well as reveal the risk factors that may influence their offending. It proposes that women and men have distinct pathways into the criminal justice system, and for women, the common pathways to offending are based on survival (of abuse and poverty) and substance abuse.

Evidence supporting gendered pathways has largely been developed using qualitative methodologies, such as rich, in-depth interviews with small samples of women in the criminal justice system. However, quantitative research has emerged that has also found support for this perspective.

Understanding the unique factors that may compel women to commit crime has practical implications in that it may guide the current practice of correctional risk/needs assessments, facilitate assessment-driven case management, and aid the development of more comprehensive and successful programs and interventions for justice-involved women.

Components of Gendered Pathways

When researchers recorded and explored the experiences of women prior to their criminal justice involvement, several components were identified

in the gendered pathways research, which were believed to produce and sustain female criminality. These include histories of personal abuse, mental illness, substance abuse, economic and social marginality, homelessness, and relationships. The gendered pathways paradigm seeks to explain how specific external circumstances experienced by women offenders (e.g., abuse and trauma, poverty, dysfunctional relationships) generate internalized behaviors (e.g., substance abuse and/or mental health issues) that tend to result in various externalizing behaviors such as drug use, theft, prostitution, assault, robbery, or other criminal behavior. Many feminist scholars view these externalizing behaviors as criminalized survival strategies. Examining the components found in these life histories has revealed different pathways to crime and prison, each with specific risk factors that drive these pathways.

One of the most notable risk factors mentioned in the gendered pathways literature is victimization. Childhood and adult victimization are viewed as important in the etiology of female delinquency and criminal behavior. For example, scholars propose that girls and women who have been victimized engage in survival strategies that bring them in contact with the juvenile or criminal justice system. Girls may experience abuse in their home so they run away. While on the streets, they may engage in survival behaviors such as prostitution, theft, and drug use that may bring them to the attention of the juvenile justice system or escalate into crime in adulthood. Experiencing abuse and trauma may also lead to the development of mental health symptoms, which, if left untreated, may lead to a girl or woman to use drugs or alcohol to *self-medicate*. This coping strategy may lead to addiction and bring her in contact with the juvenile or criminal justice system, either through the use of illegal substances or engaging in illegal activities to support her drug habit. These and other pathways have been well-documented in both the qualitative and quantitative research that has explored gendered pathways.

Qualitative Research Contributing to Gendered Pathways

Many scholars have used qualitative methodologies that have found support for girls' and

women's unique pathways to offending behavior. For example, Meda Chesney-Lind has regularly proposed that girls or women take very different pathways into the system compared to their male counterparts. The development of this argument was built upon the extensive interviews of Chesney-Lind and her colleagues with girls and women in the juvenile and criminal justice system. These interviews illustrated how the experiences of adult women in prison underscored the important links between women's childhood victimizations and their later criminal involvement. She found that many women in the criminal justice system were the victims of childhood physical and/or sexual abuse in their homes and that this compelled these women to run away. Once they were on the streets, they engaged in prostitution, petty property crime, and drug use. As adults, the women continued these activities since they were un- or undereducated and had virtually no marketable occupational skills. Other scholars have drawn similar conclusions regarding the gendered experiences and subsequent offending behavior.

For example, Regina Arnold interviewed 50 African American women serving sentences in a city jail and 10 African American women in prison to examine how these women, in her view, refused to accept or participate in their own victimization. She argued that for young African American girls who had a lower socioeconomic status, involvement in survival behavior was viewed as active resistance to their victimization. That is, many of the women in the sample had severe trauma and abuse histories, which subsequently compelled them to run away from home, steal, and leave school. These activities brought them to the attention of the juvenile justice system, parents, and legal guardians, and the process of criminalization began. Sustained criminal involvement then became the norm and a coping strategy, with drug abuse being a way of dissociating from what they had to do to survive on the streets, and committing crimes was a way to support their drug habit.

The most notable work that discusses gendered pathways is Kathleen Daly's analysis of women entering into felony court. She examined the presentence investigative reports of 40 women to discover the situations and environments that may have brought them in contact with the criminal

justice system. From these reports, Daly described five unique pathways, which included (1) *harmed and harming* women, who were either abused or neglected as children, were labeled as *problem children*, acted out, and may have substance abuse and psychological problems; (2) *street* women, who experienced abuse as children that compelled them to run away from home, and while on the street engaged in petty crimes to survive, subsequently becoming addicted to drugs and engaged in criminal behavior to support their drug habit, which contributed to their extensive criminal histories; (3) *battered* women, whose involvement in the criminal justice system was a result of being engaged in an abusive relationship with a violent man; (4) *drug-addicted* women, whose involvement in the criminal justice system was fairly recent and a result of using or selling drugs in their relationships with significant others or family members; and (5) *other*, who were women who did not fit any of these profiles. The lawbreaking of the women in this last group did not have abuse histories, mental health issues, or substance abuse problems, so their criminal behavior appeared to be motivated by greed.

Quantitative Research Examining Gendered Pathways

In addition to these and other qualitative studies that explore gendered pathways, quantitative analyses of this paradigm have emerged since 2006. Michael Reisig, Kristy Holtfreter, and Merry Morash examined the predictive validity of the gender-neutral risk/needs assessment, the Level of Service-Revised, for women who had been determined as following a gendered *pathway* to their recent felony conviction. Using Daly's framework, the authors used official sources (i.e., correctional personnel, presentence investigative reports, participant reports) to create *biographies* for each woman. Using these biographies, they determined whether each woman fit into one of Daly's gendered pathways. Their analysis revealed that for the three fourths of the women who could be grouped in four of the gendered pathways (i.e., street women, drug-connected women, battered women, and harmed and harming women), the Level of Service-Revised was unable to accurately predict their recidivism. Since the Level of

Service-Revised is a risk/needs assessment that is based on a traditional criminological theory (social learning theory), this suggests that traditional theories may not accurately address the causes of some women offenders' criminal behavior, particularly if the risk factors are gendered.

Emily Salisbury and Patricia Van Voorhis also used Daly's framework when they explored gendered pathways in a sample of adult women probationers. The results of the study statistically supported three gendered pathways to women offenders' incarceration: (1) a childhood victimization pathway that began with childhood abuse contributed to past and current forms of mental health issues and substance abuse; (2) a relational pathway in which women's dysfunctional relationships with significant others contributed to their adult victimizations, reductions in self-efficacy, and current mental health issues and substance abuse; and (3) a social and human capital pathway in which women's issues involving self-efficacy, family support, and education, as well as dysfunctional relationships, contributed to difficulties with their employment and financial statuses and consequent incarceration.

Other support for gendered pathways has been found using statistical methods that generate typologies, or subgroups, of justice-involved women and girls. These subgroups are interpreted as these women traveling a specific *path* into criminal justice involvement. For example, Tim Brennan, Markus Breitenbach, William Dieterich, Emily Salisbury, and Patricia Van Voorhis used data containing gender-neutral and gender-responsive risk factors to examine whether certain paths or subgroups found in the pathways literature existed in a large sample of female inmates. Their analyses produced eight distinct paths or subgroups of women inmates, four of which reflecting gendered pathways have been discussed in both the qualitative and quantitative literature. These four paths were characterized by abuse experiences, mental health issues, substance abuse problems, and abusive and dysfunctional relationships with significant others.

It should be noted that most of the research that has been generated supporting gendered pathways has been conducted with women-only samples. Some critics contend that if these are gendered pathways that are important for women

only, then research should be done to compare men and women to discover if these are indeed relevant for women only. Some research has emerged to address this issue by including male comparison groups. For example, Natalie Jones, Shelley Brown, Kayla Wanamaker, and Leigh Greiner used multidimensional scaling to explore the thematic structures and criminal backgrounds of a male and female juvenile probation sample and discovered a gendered pathway for girls only, one that, among other things, included elements of abuse, mental illness, and substance abuse. In another study, Krista Gehring used path analysis with data collected from a gender-responsive needs assessment to explore whether there were gendered pathways to pretrial failure for a sample of male and female pretrial defendants. The researcher found the presence of a pathway to pretrial failure that included childhood abuse, historical indicators of mental illness, and substance abuse for the female defendants only.

Gendered Pathways and Policy Implications

Research supporting gendered pathways illustrates that there are gender-specific risk factors (i.e., child abuse, mental health, and substance abuse) that contribute to women's criminal justice involvement. This can inform the development of both criminal justice risk/needs assessment instruments, case plans, and interventions for women. Risk/needs assessments should be based in theory and include risk factors that research suggests are linked to criminal behavior; therefore, many scholars suggest that gendered pathways should also be considered when developing risk/needs assessments for women. Gender-responsive risk/needs assessment instruments like the Women's Risk/Needs Assessment and the Service Planning Instrument for Women have incorporated gendered pathways into their development, but these are but a few among many risk/needs assessments that are used by criminal justice agencies.

Once a gender-responsive risk/needs assessment is implemented, case managers can use the assessment results to generate purposeful case plans. Interventions that target various components of gendered pathways such as abuse and trauma, mental health issues, substance abuse,

dysfunctional relationships, and financial instability should be included in these case plans. Identifying and attending to issues proposed in the gendered pathways literature is crucial for preventing girls and women from entering and cycling through the juvenile and criminal justice systems.

GENERAL VIOLENCE IN PRISONS

Violence in prison includes homicides, physical assaults, sexual assaults, fighting, rioting, possession of weapons, and the threats or attempts of these in prison. Although violence can and has been perpetrated by staff, it is mostly an unstudied topic and not much is known about prison staff violence. Prisoner violence has been well studied and is the main topic of this entry. Studying prison violence is important because violence has extremely high costs—in staff's and prisoners' lives, in physical injury, in emotional damage to its victims, in monetary costs to prisons as well as

state and federal governments, in the lengthening of prison sentences and the increased use of high-security options including supermax prisons, and ultimately in decreasing the safety of communities. This entry includes information on the prevalence of prison violence, its causes, consequences, and possible solutions.

Prevalence of Prison Violence

To understand the prevalence of prison violence, one must examine not only prisons' official statistics of violence but also victimization surveys. Much prison violence, with the exception of homicide, is not reported by either staff or prisoners. Staff do not report it for various reasons: not caring, addressing the violence on their own, protecting fellow officers and favored prisoners, and keeping themselves safe. Prisoners do not report because it violates the inmate code, making them a snitch; they fear reprisal; they view being victimized as embarrassing and emasculating; and they fear being labeled as weak and thus a greater target for subsequent disrespect and victimization. Only a very small proportion of prisoner victims ask for and are placed in protective custody for their safety. Actual occasions of violence that end up in official reports are more likely to occur in public areas of the prison where they are witnessed by staff, have been brought to the attention of prison administrators due to serious injury, or are reported by prisoner informants. The dearth in official reporting of violence is further exacerbated by definitional issues and the tendency by some prison systems to minimize their level of violence.

In the United States, official rates for prison homicide (seven per 100,000) are lower than homicide in the community (11.2 per 100,000). Assault rates on prisoners are higher (28 per 1,000) than assault rates on staff (14.6 per 1,000). However, various victimization surveys and research studies put the level of actual physical victimization at much higher rates, to between one tenth and one third of inmates. Prisoner Rape Elimination Act studies have found sexual assault to affect almost 5% of prisoners.

Most of the violence perpetrated occurs in male prisons; however, violence does occur in female prisons as well. Victimization rates of

female prisoners can be similar and sometimes higher than those of men, though across their entire incarceration, women usually experience less victimization than men. Overall, female prisoners are less likely to be violent than their male counterparts.

While interpersonal violence is more frequent than collective violence, the latter was ubiquitous during the 1970s and the 1980s. During these riots, prisoners demanded improved conditions of confinement; increased opportunities for work, education, and treatment; as well as other changes in rules, amenities, and prison procedures. Although much of the violence during this period involved property damage, work stoppages, and the takeover of parts of prisons, others were full-scale riots. Prisoners and prison staff were killed and injured and property extensively damaged, including the burning of parts of buildings. Riots occurred at Attica Prison (New York) in 1971, the New Mexico State Penitentiary in 1980, and the U.S. Penitentiary in Atlanta, GA, in 1987, as well as prisons across the globe.

Causes of Prison Violence

Prisoner Characteristics

The majority of research on prison violence has focused on the characteristics of prisoners who perpetrate violence. These include static characteristics that are inherent or cannot be changed as well as dynamic ones that may be altered to decrease violence.

Static Characteristics

Age has been found to be the strongest predictor of prison violence—younger prisoners are more likely to be involved in violence than older prisoners, using aggressive and sometimes preemptive tactics when faced with potential danger. Older prisoners tend to avoid violence at all costs. Three other strong predictors of prison violence are prior incarceration, history of prison violence, and prior gang affiliation. Although prior gang affiliation is static, prison and future gang affiliation could be considered dynamic characteristics. The study of the relationship between prison violence and race, ethnicity, marital status, or offense type has yielded mixed results.

Dynamic Characteristics

One set of dynamic characteristics that affects whether or not a prisoner is involved in violence is his or her coping strategies. Most prisoners experience stress during their incarceration. However, those with less positive or negative coping strategies are more likely to resort to violence when faced with stressful events or circumstances. Prisoners who elicit emotional and instrumental support from family, fellow prisoners, and prison staff are less likely to engage in violence in general. Other positive coping strategies that reduce violence include a general attitude accepting that problems exist for all of us, behavioral disengagement when interpersonal conflicts occur, and positive problem-solving, helped by open communication. Negative coping in prison includes venting one's emotions, the use of humor or tough bravado, and negative or absent problem-solving skills.

Since access to mental health records of prisoners is rare, the study of the relationship of mental illness to prison violence is lacking. Nevertheless, prisoners with indicators of mental illness (e.g., self-reports; evidence of treatment and medication) have been linked to violence and placement in supermax prisons. The correlation between anger, anxiety, or substance abuse and prison violence is also unclear.

Gresham Sykes discussed how the hierarchy of prisoners affected violence in the Trenton State Prison (New Jersey) in the mid-1950s. He labeled those who perpetrated different types of violence as toughs, hipsters, gorillas, and wolves and those who were victimized as weaklings, fish, and punks. Most penologists now refer to the small percentage of prisoners who perpetrate the largest percentage of violence as predatory convicts. Among these perpetrators who enjoy violence and use it to gain power are the state-raised youths. Raised in foster care and juvenile facilities, they lack the love and prosocial upbringing, causing them to be inordinately angry and unable to cope, perpetrating violence on both staff and fellow prisoner alike.

Institutional Causes

Although less studied, there are institutional causes of prison violence. For example, higher security prisons (e.g., maximum or supermax) are

more violent than lower security prisons. Prison architecture that includes blind spots, poor lighting, and antiquated technologies produces more violence. Some believe that dreary, dirty prison conditions negatively affect the moods of both prisoners and staff, exacerbating violence. Research on the relationship between overcrowding and violence is mixed; yet, boredom is a clear predictor of violence. Researchers have found that the racial and ethnic compositions of both staff and prisoner populations affect violence, as do the prisoner collective propensity, high staff turnover, and prisons with transient, unsettled prisoner populations. Administrators' decisions on regimes and their responses to events have been found to attenuate and exacerbate both collective and interpersonal violence. Finally, correctional staff can aggravate prison violence through disrespectful and inhumane treatment of prisoners, inadequate communication skills, and ignoring prisoner violence and prisoner needs.

Situational Precipitators

Prisoner characteristics and the prison environment can interact in certain ways as to promote or mitigate prison violence. Prisoners do not act in a vacuum but take into consideration many factors and thus may behave differently depending on their location, the type of prison, and their surrounding circumstances. In many prisons, mostly young, urban males have imported their street culture into prisons, often leading to a replication of street violence in prison yards. Their campaign for respect supports the use of violence to exact respect and build reputations and is exacerbated by the hypermasculine culture of prison that eschews weakness and promotes a tough and unemotional exterior. Researchers have found that certain activities such as gambling, strong-arming, the black market, and the presence of contraband, especially drugs, increase the level of violence. When staff allows these activities to exist and do not address bullying and conflicts between inmates, violence flourishes.

Consequences of Prison Violence

The most obvious consequences of prison violence are physical injury, the need for medical attention

and hospitalization, and possibly death. Prison violence also causes emotional damage to prisoners in the form of increased depression and anxiety, fear, and post-traumatic symptoms such as insomnia, nightmares, hypervigilance, flashbacks, detachment, and lack of energy. The fear of violence can be disabling and prisoners who are fearful and focused on keeping safe are less likely to focus on improving themselves through education and rehabilitation. Finally, prison violence can have debilitating effects on prisoners' health and contributes to prisoners' self-harm, including attempted and successful suicide. Prisons in which violence is ubiquitous tend to breed men and women who are more prone and willing to commit violence themselves.

The consequences of prison violence do not remain in the prison. Released prisoners who have been victimized by violence and/or who have perpetrated violence to ensure their safety are likely to experience its aftereffects. The anger, depression, and anxiety from fear of violence in prison could continue to affect their behavior, especially during the early part of their community reentry. People who have become violent or more violent in prison are more likely than those who have not become violent or more violent in prison to bring that violence into their homes and communities, increasing cycles of violence and contributing to increased levels of violence in the community.

Addressing Prison Violence

When prisoners are caught perpetrating violence, they typically are charged with a disciplinary infraction and proceed through the prison's disciplinary process. If the violence is significant, they may also be charged with additional crimes. Possible sanctions include punitive segregation or classification to administrative segregation or supermax prisons. The concentration of violent, disruptive, and unmanageable prisoners in supermax prisons began in the late 1990s, reducing the use of dispersion of problem prisoners to out-of-state or faraway prisons.

The prevention of prison violence is not easily obtained. Prisons can enact strict search procedures for visitors and staff as well as regular searches in prisons for weapons. Prisons that have implemented direct supervision, unit management, and the proper classification of prisoners have decreased

their overall prison violence. In addition, prisons that provide education, prosocial activities, and treatment programming counteract boredom that often leads to negative behavior. Technology such as cameras, scanners, and transponders that locate violent prisoners may augment violence prevention. The Prison Rape Elimination Act, passed by the U.S. Congress in 2003, mandates that prisons develop zero-tolerance policies toward sexual assault and processes that ultimately detect, prevent, and punish prisoners and staff who engage in it. Prisons are mandated to report annually on the actual incidents of sexual assault that come to their attention as well as to allow annual sexual assault victimization surveys. The same attention to general interpersonal violence is warranted as is the assurance that disciplinary processes and prison regimes are just procedural. Similarly, prison administrators can ensure that staff–inmate relationships are based on respect, communication, and structure and that prison staff are properly trained and supported.

Prison administrations can also reduce the atmosphere of violence by taking measures that reduce fear. This includes tracking and monitoring gangs and strict supervision of gang members who perpetrate violence. But it can also include other measures—housing decisions that attenuate fear; staff vigilance; and the proper assessment, supervision, and treatment of young offenders. Some prisons have had success in decreasing violence through anti-bullying programs or through the use of incentive initiatives. Administrators can also address the needs of their mentally ill prisoners, who can be both victims and perpetrators of violence, by properly identifying, housing, and treating them. Prisons can also help all prisoners cope with the stresses of prison by increasing family support, staff involvement to help prisoners solve their problems, and by changing prisoners' criminogenic thinking by offering prisoners cognitive behavioral therapy. Although the causes of prison violence are many, the potential avenues for reducing violence are similarly abundant.

GENETIC AND ENVIRONMENTAL INFLUENCES ON VIOLENCE AND AGGRESSION

Since the early 20th century, the expansion of the field of criminology has contributed substantially to understandings of aggression, violence, and criminality. However, those contributions now appear incomplete with recent methodological advancements occurring within other disciplines. This assessment stems from the reliance on standard social science methodologies (SSSMs) in criminology. From topic and sample selection to statistical analyses and interpretation, SSSMs rest on the assumption that social processes alone are responsible for variance in personality and behaviors. While in the past, this assumption went unchallenged in criminology, recent empirical examinations have confronted the fundamental properties of the SSSM approach. Specifically, since the early 2000s, researchers within biosocial criminology have begun to argue for the

elimination of the blank slate assumption from criminological assessments and a recognition of how individual differences impact the propensity toward violence, aggression, and criminal conduct. Biosocial criminology typically employs the methodologies of behavioral and molecular genetics in assessments of the causes of aggression and violence. This entry provides a synopsis of the intellectual advancements generated from the use of behavioral and molecular genetics in the field of criminology. The entry begins with an overview of the fundamental principles of behavioral and molecular genetics and concludes with a review of some of the general research findings assessing the genetic and environmental effects on aggression and violence.

The Foundations of Behavioral and Molecular Genetics

The concentration of behavioral and molecular genetics can be concisely described as the dissection of the phenotypic variance observed within a group. Phenotypic variance refers to the observable differences on a single trait between individuals within a population. Both behavioral and molecular genetics rest on the assumption that phenotypic variance is influenced, to varying degrees, by two factors: genetics and environment.

At this point, it is important to differentiate between behavioral and molecular genetics. Behavioral geneticists are often most interested in the additive and nonadditive (i.e., dominant) effects of genetic factors on phenotypic variance (the heritability component of behavioral genetic equations), whereas molecular geneticists are interested in assessing the direct or interactive effect of one or more specific polymorphic genes. Importantly, although the two approaches differ, they still incorporate environmental factors into their analyses.

In discussing environmental factors, these approaches also recognize that the uniformity of environmental influences presented in research based on a SSSM is misguided. Thus, environmental factors are bifurcated into two different categories: the shared environment and the nonshared environment. An easy way to conceptualize these factors is to think of two siblings. The shared environment represents those nongenetic factors that

are the same between the two siblings and that serve to make them more phenotypically similar (e.g., socioeconomic status). The nonshared environment, in contrast, refers to all nongenetic factors that are unique to each sibling and serve to differentiate the siblings on any given phenotype (e.g., different peer networks). Behavioral geneticists employ a variety of methodological and statistical strategies to determine the proportion of phenotypic variance within a population attributed to genetic (heritability) and nongenetic (shared and nonshared environments) factors but the most common is the study of twins.

Twin studies generally include a sample of monozygotic (MZ) and dizygotic (DZ) twins. When general assumptions are held (e.g., random mating and an equal environment within the dyads), MZ twins and DZ twins differ from each other in only one way: MZ twins share 100% of their genetic information while DZ twins share, on average, 50%. Thus, the logic underlying the twin methodology is simple. If, when comparing groups of MZ twins to groups of DZ twins, observations suggest greater phenotypic similarity among MZ twins than DZ twins, it indicates that genetic factors are more influential on the phenotype under study. Conversely, if greater phenotypic similarity is observed among DZ twins than MZ twins, it suggests that environmental factors are more influential.

Relying on this logic, various statistical techniques are employed in twin studies to estimate the proportion of the phenotypic variance explained by genetic factors, the shared environment, and the nonshared environment. Thus, using conceptually sound and methodologically valid techniques, phenotypic variance is decomposed into the three factors that account for 100% of the differences in the phenotype under study within a population. For example, the univariate ACE model is a structural equation modeling technique used for assessing the quantity of variance within a single phenotype explained by genetic factors (A), the shared environment (C), and the nonshared environment (E). It generates estimates of the phenotypic variance explained by each factor through the statistical comparison of a more genetically similar group and a less genetically similar group, generally MZ and DZ twins. The technique can also include the trimming of

elements from the model (typically by dropping either A or C) and the use of model fit statistics to determine which of the parameters has the most substantial influence on phenotypic variance.

While the ACE model is employed to partition the variance in a single phenotype, a similar model can be used to determine the genetic and nongenetic influence on the covariation between two phenotypes. Known generally as the Cholesky model, this approach generates estimates of the phenotypic variance within a multivariate relationship for genetic and nongenetic influences. As an extension of the statistical properties of the ACE model, the Cholesky model generates A, C, and E estimates for multivariate relationships by assessing the concordance and discordance of a multivariate relationship within twin pairs.

Although the ACE and Cholesky models, as well as designs such as adoption and family/pedigrees studies, are valuable in discerning the relative influence of genetic and nongenetic factors on univariate and multivariate phenotypic variance, they do not provide information regarding the effect of isolated factors. Fortunately, a method known as *MZ discordance*, which allows for the isolation of nongenetic factors that affect an outcome, can be employed. The logic is simple: Given that MZ twins share 100% of their DNA and, by definition, 100% of their shared environment, the only reason for within-pair discordance on a phenotypic outcome is due to nonshared environmental factors. Thus, utilizing different statistical techniques (e.g., difference scores or saved residuals in regression models), researchers can indicate which nonshared environmental factors affect an outcome while simultaneously controlling for the potentially confounding effects of shared genetic and nongenetic factors. The method is a highly effective way to determine potentially causal relationships between nongenetic variables and phenotypic outcomes.

Similarly, molecular geneticists employ methods wherein they isolate the direct and interactive effects of specific polymorphic genes. By using techniques such as candidate gene analyses, genome-wide association studies, and genome-wide complex trait analysis, researchers can identify which groups of genes as well as which individual genes impact phenotypic variance. In addition, researchers in this area employ

gene–environment interaction methodologies to assess the differential effect of genetic polymorphisms across environmental contexts (and vice versa).

Genetic and Environmental Estimates of Aggression and Violence

Both individual studies and meta-analyses have illustrated the differential effects of genetic and nongenetic factors on aggression and violence. For example, a study by John Philippe Rushton in 1996 estimated that approximately 55% of the variance in violent behavior among adult males was accounted for by genetic factors with the remaining variance (45%) explained by nonshared environmental factors. Importantly, Rushton also observed that for females, the nonshared environment accounted for the totality of the variance in violent behavior. Thus, Rushton illustrated the differential effect in which genetic and nongenetic factors can influence males and females. More recently, a study by James Christopher Barnes and colleagues in 2013 assessed the genetic influence on a specific type of violent behavior: intimate partner violence. The authors found that between 20% and 54% of the variance in behaviors such as hitting, injuring, and sexually assaulting one's partner is accounted for by genetic factors. Molecular genetic analyses have also illustrated the influence of genetic factors on violence. For example, a study by Hexuan Liu and colleagues in 2015 illustrated the various ways in which individual genes and the collective effect of multiple genes interact with a variety of social outcomes to influence variance in violent behaviors.

In their meta-analysis that included 24 different genetically sensitive studies, Donna R. Miles and Gregory Carey in 1997 concluded that up to 50% of the variation in aggression is accounted for by genetic factors. The authors noted that their results did not support such theories regarding aggression as social learning, which emphasizes the role of shared environmental effects. More recently, in a massive undertaking, Tinca J. C. Polderman and colleagues in 2015 conducted a meta-analysis of 50 years' worth of twin studies covering virtually every studied phenotype. Overall, the authors indicated that about 50%, on average, of any given phenotype is accounted for

by genetic factors. In findings related to aggression and violence (conduct disorder), the authors found that approximately 49% of the variance could be accounted for by genetic factors, 18% by the shared environment, and about 33% by the nonshared environment.

In an effort to isolate nongenetic influences on the variance in aggression and violence, some researchers have employed the aforementioned MZ discordance method. For example, a study of Sybil Alexandra Burt and colleagues in 2009 indicated that those twins who had greater exposure to delinquent peers during early adolescence (relative to their co-twins) also displayed greater externalizing behaviors (including aggression and violence) over the course of their adolescence. Similarly, a study of Kevin M. Beaver in 2008 illustrated that twins who reported a greater number of delinquent peers relative to their co-twins also reported greater involvement in delinquency during adolescence (but not adulthood). As a reminder, these findings indicate the influence of an *environmental* effect (e.g., delinquent peers) after the influence of shared genetic and shared nongenetic effects have been controlled. Thus, these analyses provide robust evidence for the influence of delinquent peers on the variance in aggression and violence (especially during adolescence).

Moving Forward

This entry has highlighted the shortcomings of the SSSMs and the benefit of a biosocial approach to studying the etiologies of aggression and violence. While not an exhaustive review of the literature in this area, the entry illustrated two important points. First, in using behavioral and molecular genetic methodologies, researchers are more adept (relative to purely social approaches) to uncover the complex nexus of factors underlying variance in aggression and violence. Second, such approaches allow not only for the identification of genetic factors but also for a more rigorous and statistically sound manner to identify *environmental* factors that influence the development of aggression and violence. In accomplishing these two important facets of research, studies that employ a biosocial approach lead to better understanding of aggression and violence and thus

better informed policies and programs directed at reducing the financial, psychological, and societal costs associated with these antisocial outcomes.

GLOBAL IMPRISONMENT

The institution of the modern prison is an invention of the early 19th century. As such, it was inspired by the ideas of the enlightenment and religious reform movements and was generally an attempt at alleviating the plight of prisoners, helping them reform for a life without crime, and integrating them into the emerging world of industrial societies. The prison turned out to be one of the most successful institutions ever and is certainly the most widely adopted criminal justice institution. Its diffusion across the globe was unprecedented in terms of its velocity and the diversity of contexts in which it took hold despite great cultural, political, and economic differences, and a mounting lack of evidence that it, in fact, could achieve its objectives of reforming prisoners or deterring future crimes. It was seen as a promising solution to problems of crime and punishment at the beginning of the Industrial Era and as a penal technology that befitted the requirements of the emerging powerful nation and colonial states.

The prison is now an integral part of criminal justice institutions across the globe. However, countries differ widely in their use of imprisonment for different types of offenses, the number of individuals incarcerated, the social groups that are most affected, prison living conditions, and the provisions available for prisoners' well-being and rehabilitation. The global landscape of imprisonment is shaped by these differences, and according to Jan van Dijk, the divisions between global regions reveal a justice deficit in conjunction with a *North-South security divide* that mainly affects developing countries in the southern hemisphere. In many countries in this global region, living conditions in prisons are life-threatening, often due to endemic violence. In this entry, the major problems of contemporary global imprisonment are addressed, including overcrowding, human rights issues, and the situation of female prisoners.

Incarceration Rates

Present estimates of the world's prison population are between 9 and 10 million, which amounts to a rate of at about 152 prisoners per 100,000 of the population globally. Between 1990 and 2013, the

number of prisoners increased overall by 25%. This general trend between 1990 and 2013 affected member countries of the Organisation for Economic Co-operation and Development mainly in the northern hemisphere, with an increase of nearly 40%. This is mirrored in a number of countries in poorer regions, such as in Asia, a region that experienced a similar increase. While the prison population of the Americas increased by 50%, it did not change in Africa during this time. Half of the world's prisoners are held in prisons in the United States, China, and Russia. The United States has the highest imprisonment rate with more than 700 per 100,000 people; this is more than 4 times the global average. With just 5% of the world's population, the United States houses 25% of the global prison population. This mass incarceration is unique in the history of criminal justice, if concentration camps, labor camps, and other types of detention are not included as part of criminal justice institutions.

When global regions are compared, the Americas have the highest imprisonment rates, with an average of 234 prisoners per 100,000 of the population. This is followed by Europe with 156 prisoners per 100,000. Africa has the lowest imprisonment rate of all global regions with an average of 109 prisoners per 100,000. Generally, wealthy and developed countries use imprisonment more frequently and have higher imprisonment rates than poorer countries due to the costs of imprisonment. However, significant differences exist within global regions. In Europe, for example, wealthy Scandinavian countries, with their widely acclaimed prison systems, have the lowest imprisonment rates. Postcommunist Eastern European countries have the highest rates in this region. In Africa, both Central and West Africa have the lowest imprisonment rates of the continent with, respectively, 64 and 60 prisoners per 100,000 of the population. In contrast, in the southern part of Africa, the rate is nearly 4 times as high with 230 prisoners per 100,000 of the population, due to extremely high numbers of prisoners in South Africa.

Prison Overcrowding

The increase of the world's prison population has caused severe problems of overcrowding across

the globe. In 60% of 191 of the world's countries for which data are available, the prison system exceeds intended capacity. Some countries, such as Kenya and Haiti, incarcerate 3 times as many inmates as there are prison beds. Such overcrowding affects not only adult prisoners but also children and young people. It is most acute in African and Latin American countries. Post-conflict countries like Rwanda are afflicted, as are the Central American countries of Ecuador, Haiti, and El Salvador, which have high levels of gang and drug violence.

Overcrowding, however, is not simply a consequence of high crime rates. Often, it is the result of dysfunctional and understaffed criminal justice systems. Pretrial detainees often linger in prison longer than the actual sentence they would receive. In numerous countries, pretrial detainees account for more than half of the prison population, also causing the most serious overcrowding. African countries (e.g., Liberia, Mali, Benin) have the highest proportion of pretrial detention, followed by Latin American countries (e.g., Haiti, Bolivia, Paraguay). There is a global overuse of pretrial detention, which accounts for a considerable proportion of the increase in global imprisonment over the past decades.

International Prison Rules

Prisoners are a vulnerable population due to their powerlessness at the hands of state authorities. Because of this, prison conditions are often viewed as indicative of the human rights regime to which a country adheres. At the turn of the 20th century, for both Winston Churchill and the Russian writer Fjodor Dostojevsky, the conditions in prison epitomized what they called the *civilization* of a country. The international community and its organizations have developed rules and regulations for life in prisons, including vital and basic provisions such as space, food, hygiene and health care, and contact with family and society. The United Nations (UN) Standard Minimum Rules for the Treatment of Prisoners (SMRs) were initially adopted in 1955 and approved in 1957. Major developments in human rights and criminal justice practices led to revised SMRs, known as the *Nelson Mandela Rules*, which were adopted unanimously by the UN General Assembly in

2015. The Mandela Rules now include a set of Rules for the Treatment of Women Prisoners and Non-Custodial Measures for Women Offenders (the Bangkok Rules), which the UN General Assembly adopted in 2010. Seventy principles address the specific experiences and needs of women in custody, including their safety from sexual assault and violence, their physical and mental health, and care for children while in custody.

With its Convention against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment, the UN developed a further instrument to regulate and monitor the treatment of any individual in detention and at the hands of criminal justice or other officials. The Convention was adopted by the UN in 1984 and came into effect in 1987. However, it took nearly another two decades until, in 2006, the UN followed the example of the European countries and the Council of Europe, which had adopted the Optional Protocol to the Convention against Torture and other Cruel, Inhuman or Degrading Treatment or Punishment in 1987. This protocol is the essential mechanism to monitor compliance with the Convention. It requires that signatory countries agree to visits to any type of detention center in their responsibility on a regular basis. Independent international and national bodies select and visit places where people are deprived of their liberty and issue reports. A subcommittee of appointed international experts oversees this process.

Prison Conditions and Human Rights

Taken together, the SMRs and the Optional Protocol address basic needs of prisoners and monitor their human rights. The Country Reports issued by the U.S. State Department, as well as reports by Amnesty International, give the most comprehensive overview of prison conditions and compliance with human rights worldwide. These form the basis for an Index of Prison Conditions that ranks these conditions from meeting the SMRs to being life-threatening. Conditions are rated life-threatening if violence at the hands of officers and/or other inmates is rampant and has led to deaths in custody. Conditions pose equally lethal threats when infectious diseases (e.g., tuberculosis) can spread without sufficient health care or

where sexual violence is frequent in HIV-infected prisons. Conditions are particularly detrimental in overcrowded prisons in developing countries in the southern hemisphere.

According to the Index of Prison Conditions, prison conditions are best in Europe and worst in Africa, where prisoners often are at high risk of life-threatening conditions while in prison. Asia and Oceania have better conditions than Latin America. Many countries across Africa and Latin America have life-threatening conditions, partially due to serious overcrowding and partially due to unsafe conditions, organized gang violence, and absence of health care. Prison conditions distinctly differ within global regions. While Western European countries have the best prison conditions that, on average, meet the SMRs, Eastern European countries have harsh conditions (even if these are not typically life-threatening). In Latin America, Caribbean countries have slightly better prison conditions than countries in South and Central America. Visits from family and friends seem to be more generously permitted in African and Latin American countries, however, partially because family members provide food and care. Prisons in Latin America are less regulated and often lack effective security and oversight. On one hand, these conditions grant more liberty to prisoners; on the other hand, they are responsible for gang violence and organized crime within the prisons.

Human rights for prisoners also differ widely across the globe. This concerns the compatibility of life imprisonment (without parole) with basic human rights and human dignity, the space available to prisoners, the use of solitary confinement, and their voting rights. In the majority of European countries (70%), prisoners have the right to vote in elections. Global regions with the lowest proportion of countries where prisoners can vote are Africa and the Americas with 25%. In Asia and Oceania, nearly half of the surveyed countries allow prisoners to vote. In Europe, where the European Court of Human Rights repeatedly decided against a blanket ban of voting rights for prisoners, a few Western European countries (e.g., the United Kingdom) and a higher proportion of Eastern European countries prohibit prisoners from voting. In the United States, only two states, Vermont and Maine, have no restrictions on prisoners' voting rights.

Female Prisoners

Female prisoners constitute a vulnerable and particularly disadvantaged group. With 700,000 women and girls in prison as of 2015, this group constitutes between 2% and 15% of the prison population worldwide. The vulnerability and disadvantage of women prisoners result from their minority position within the prison system; experiences of abuse, violence, and victimization; special needs with regard to mental and physical health; and responsibilities as caregivers for children. A joint report by the World Health Organization and the UN Office on Drugs and Crime in 2009 addressed the systematic gender inequity in prisons.

The proportion of imprisoned women and girls among the prison population is lowest in African countries (2.8%) and highest in Asian countries (4.9%), with a global average of about 5% of the prison population. Countries with an extremely high proportion of female prisoners are Myanmar, Thailand, Vietnam, and Bolivia with proportions above 15% of the prison population. Women and girls are the fastest growing group of prisoners worldwide. Between 2000 and 2015, the number of women and girls in prison increased by 50%, while the worldwide prison population increased by 20%.

There are relatively few prisons or facilities for women, and they are often housed in prisons far away from their families. As women tend to serve shorter sentences than men, they are unable to take advantage of drug rehabilitation and other education- or health-related programs. The majority of female prisoners have been victims of sexual abuse and domestic violence. Many suffer from post-traumatic stress disorder, substance abuse, and other health problems that need to be addressed. In many parts of the world, they are exposed to sexual assault by criminal justice personnel and by prisoners. Pregnancies and birth in prison, the well-being of infants and small children in prisons, and the care for children outside of prisons are also major issues for women in prison.

Imprisonment is an important global issue. Typically (but not exclusively) in poor and developing countries, conditions in prisons do not meet SMRs, which put prisoners' lives and well-being

at risk and amounts to severe violations of their human rights. High imprisonment rates affect the social and economic lives of families and communities and burden countries' budgets across the globe. Reducing imprisonment and improving prison conditions is a major task for the international community.

GOOD LIVES MODEL

The Good Lives Model (GLM) of offender rehabilitation is a rehabilitation framework developed and refined by Professor Tony Ward and his colleagues since 2002. The GLM represents a strengths-based approach and is based on the idea that, in order for long-term change to be achievable, offenders need the opportunity for better lives—lives that are both personally meaningful and socially responsible. Furthermore, the GLM purports that the best way to construct such opportunities, and achieve these long-term

prospects, is via capability building. The model states that if offenders are to have any real chance at giving up their harmful behaviors, in lieu of living healthy, prosocial, meaningful lives, they need to be equipped to live differently. This requires the development and acquisition of knowledge, skills, and competencies across a range of domains, relevant to their physical, psychological, and social functioning.

Although the central aim of the GLM is to build psychological and social capacity, the GLM pays equally detailed attention to risk. As such, the GLM advocates for a dual emphasis on *risk management* and *goods promotion*. Put another way, application of the GLM in offender management has two associated goals:

1. *monitor the offender*—manage and reduce the risk posted by an offender to the community (risk management) and
2. *engage the offender*—enhance offender's well-being by increasing the offender's strengths and capability so that the offender is better equipped to live a prosocial and personally meaningful life (goods promotion)

The core assumption of the GLM is that rehabilitation is an evaluative and capability-building process aimed at assisting the offenders to change in a long-term capacity.

The GLM is not a model of offending behavior; it is not an etiological theory, nor does it explain the offense process. Rather, the GLM is a model of healthy human functioning. In line with positive psychology, it provides practitioners with an objective reference to what constitutes a healthy, prosocial adult life, characterized by optimal levels of well-being. A helpful way to understand its relevance for offender rehabilitation is to view it as a conceptual framework that practitioners can use to understand the offending behavior to plan positive, capability-building interventions. The framework can therefore be used to assist individuals to develop the competencies needed to pursue more fulfilling lives.

This entry begins by presenting the core concepts and the etiological underpinnings of the GLM. The entry then discusses the application of the GLM and concludes with a review of the empirical support for the GLM.

Core Concepts of GLM

Primary Human Goods (PHGs)

Central to the GLM is the notion of PHGs. PHGs are defined as actions, states of affairs, characteristics, experiences, and states of mind that are intrinsically beneficial to human beings and are sought for their own sake rather than as a means to a more fundamental end. This means that they have intrinsic value (are meaningful and valuable in and of themselves) and, in addition, they represent fundamental purposes and ultimate ends of human behavior.

PHGs represent overarching, ultimate life pursuits and are expressed in the many and varied goals that humans set for themselves. PHGs are such powerful human motivators that human beings are naturally predisposed to seek them for the sake of their overall psychological, physical, and social well-being. Therefore, the seeking of PHGs is inherently natural and valuable.

The generation of the PHGs draws from research findings and theories identified in a range of disciplines, including psychology, evolutionary theory, practical ethics, anthropology, and philosophy. Based on past and current cross-cultural and cross-disciplinary research, there are 11 PHGs. It should be noted that these PHGs have emerged from thorough analysis of the aforementioned disciplines as well as research findings related to personal strivings and the pursuit of healthy lives characterized by high levels of well-being. Given this, the GLM and its account of PHGs may be considered an evolving theory, always open to adaptation, refinement, and development, based on the ever-evolving nature of world knowledge and empirical research.

Although the following brief descriptions of the 11 PHGs are provided, Ward and his colleagues highlight the need for practitioners to understand the full definitions to ensure theoretical integrity in professional practice. It should be noted that there is no objective ranking of PHGs; they can only be subjectively ordered according to individuals' personal priorities.

1. Life (healthy living and optimal physical functioning, having one's basic needs for survival met)
2. Knowledge (based on how well informed one feels about things that are important to him or her)
3. Excellence in play (achievement and mastery in relation to hobbies and recreational pursuits)
4. Excellence in work (achievement and mastery in relation to vocational pursuits, including education and training)
5. Excellence in agency (autonomy, personal power, and self-directedness)
6. Inner peace (being emotionally competent, having emotional regulation skills, also referring to the desire people have for emotional balance and being free from emotional turmoil and distress)
7. Relatedness (including intimate, romantic, and familial relationships)
8. Community (having a broader sense of belonging and social connectedness to groups with shared interests, values, and aims)
9. Spirituality (in the broad sense of finding meaning and purpose in life)
10. Pleasure (feeling good in the here and now, hedonism, and healthy self-gratification)
11. Creativity (expressing oneself through alternative forms)

These PHGs form the foundation of human beings' ultimate pursuits. Each of one's personal, professional, and life goals can be linked to one or a combination of these PHGs. The active and successful pursuit of PHGs brings about overall life satisfaction, happiness, contentedness, and well-being across the three domains of human functioning: physical, psychological, and social.

PHGs and Offending Behavior

The GLM conceptualizes offending behavior in natural and humanistic terms. Human behavior is meaningful and purposeful and is directed by one or more overarching (even if implicit) goals. Even offending behavior has an underlying legitimate fundamental goal (good) and as such, it can be viewed in terms of the problematic pursuit of PHGs. For example, the goal of a violent crime at face value might appear to be for the purpose of inflicting of harm on another, but in actuality, the violent behavior is a (problematic) means to some

other legitimate end. Perhaps the goal was to regain a sense of personal power, to take control, to feel respected, to feel admired, to hold a valued place in a gang or perhaps to resolve some kind of negative emotional state. These are normal states for adults to pursue and in this example relate to PHGs such as excellence in agency, community, and inner peace. However, it is the way in which these goals are achieved which is problematic, and therefore, it is the strategy or means that is the target for intervention, and the associated capabilities, rather than the goal itself or the PHGs implicated in the offending.

Etiological Underpinnings of GLM

In explaining why people offend—that is, why people use problematic means for an otherwise legitimate goal—the GLM identifies capabilities, or specifically, their absence, as the primary source of dysfunction. An absence of capabilities typically means that the person has deficits or problematic characteristics in place of adaptive ones. These deficits or weaknesses can be internal or external. Internal factors refer to the person's skills, attitudes, beliefs, psychological characteristics, and physical health, whereas external factors refer to environmental, social, cultural, and interpersonal opportunities and circumstances. As offenders often lack the strengths and positive attributes and environments to overcome their life's challenges prosocially, they act in antisocial ways, symptomatic and reflective of their unique profile of deficits and obstacles. Remembering that PHGs are such powerful human motivators that all human beings are naturally inclined to seek them, the GLM argues that people offend in the pursuit of PHGs but do so in harmful ways due to their individual set of internal and external deficits and obstacles. Those internal and external deficits that drive offending behavior in the pursuit of PHGs arguably represent an individual's unique set of criminogenic needs (i.e., dynamic risk factors).

Using the GLM to Work Meaningfully With Offenders

The GLM purports that if one understands what the offender was or is seeking when he or she offends, in terms of PHGs, then one understands

what motivates this person and what the person really values and desires for himself or herself. Deciphering the legitimate goal in offending behavior means that practitioners can understand the PHGs that the offender was seeking, resulting in tailored intervention and rehabilitative efforts to help the offender to build capacity in precisely those areas that are underresourced. By helping the offenders to build the necessary conditions (i.e., internal and external capacities) to fulfill their needs and pursue their PHGs in adaptive, prosocial ways, the associated effect is that they will be less likely to harm others and themselves. As such, the enhancement of offender's well-being (in a goods promotion sense) directly functions to reduce risk and protect the community.

Application of GLM

The GLM has been applied to a broad range of offender populations including arsonists, female offenders, developmentally disabled offenders, violent offenders, and mentally disordered offenders. The most prevalent application of the GLM, however, has occurred within the sexual offending domain. Within this area, the GLM has been carefully set out in terms of its application in both treatment and correctional supervision and management. The goal of applying the GLM is to help offenders to develop the capacity to seek PHGs in socially acceptable and personally meaningful ways as well as to reduce and manage their risk of reoffending.

In practice, assessment begins with mapping out an offender's good lives (often implicit) plan by identifying the weightings, or priority, given to the various primary goods. This is achieved through (a) asking increasingly detailed questions about an offender's core commitments in life and his or her valued day-to-day activities and experiences and (b) identifying the goals and underlying values that were evident in an offender's offense-related actions. Once an offender's conceptualization of what constitutes a good life is understood, future-oriented strategies aimed at satisfying an offender's PHGs in socially acceptable ways are formulated collaboratively with the offender and translated into a good lives rehabilitation plan. Treatment is individually tailored to assist an offender implement his or her good lives

intervention plan and simultaneously address the criminogenic needs that might be blocking PHG fulfillment. Accordingly, intervention includes building internal capacity and skills and maximizing external resources and social supports to satisfy PHGs in socially acceptable ways.

Empirical Support for GLM

As previously discussed, the GLM was developed based on an extensive review of interdisciplinary theory and research on human functioning and healthy living. As such, it has strong theoretical and empirical foundations. In terms of empirical research on the GLM's effectiveness as applied in rehabilitative programs, there has been no direct examination of the GLM's impact on recidivism; however, several studies have demonstrated the GLM's positive impact in terms of client satisfaction and improved outcomes for those persons who completed GLM-informed programs. Regardless, there is an ongoing need for further evaluation of programs and services that operationalize the GLM and also a clearer understanding of how risk reduction is causally related to well-being enhancement and would strengthen the model.

GUANTANAMO BAY

Guantanamo Bay (GTMO) is a strip of land on the southeast tip of Cuba, which the United States leased in perpetuity in 1903, following the Spanish–American War. The 45-square-mile territory hosts a large U.S. naval installation (GTMO), that had a relatively quiet existence until the attacks on September 11, 2001, when the U.S. Department of Defense put into motion plans to utilize sectors of the base for the purpose of detaining and interrogating terrorist suspects. There, the U.S. military has held up to 780 detainees (down to 320 in 2008 and down to 41 in 2018). Many of those detainees were captured in Afghanistan in the early phases of the global war on terror. The U.S. government has insisted that many of the detainees were terrorists affiliated with the Taliban or Al Qaeda (i.e., unlawful enemy combatants) and posed an imminent threat to national security. On those grounds, the George W. Bush administration argued it had the authority to detain them indefinitely while a few detainees were considered for military tribunals. This entry introduces the emergence of GTMO and its enduring legacy of legal and human rights controversies.

Emergence of GTMO

In January 2002, when the first contingent of detainees arrived, GTMO was still a work in progress, literally. The U.S. Marines had just completed a makeshift prison known as *Camp X-Ray* consisting of dozens of rows of steel-mesh cages, ringed by a perimeter of razor-wire fence, and exposed to the elements of the Caribbean. Detainees were later transferred to newly constructed cellblocks, leaving Camp X-Ray to be slowly swallowed by the jungle.

As of 2018, GTMO comprises several detention sectors: Camp Delta (a permanent detention camp), Camp Echo (a maximum-security facility within Camp Delta), and Camp Iguana (a smaller, low-security compound located about a half-mile from the main detention area). The security force consists mostly of U.S. Army Military Police and U.S. Navy Master-at-Arms. Visiting journalists have been granted tours of some of the detention units accompanied by explanations that some parts of the camp are easier to manage than others. Camp 4, for example, is a newer wing where Level 1, or *highly compliant*, prisoners are allowed to live in communal barracks, serving their own food and moving freely in and out of small recreation yards. Some detainees are held in Camp 1, for Level 2, or *compliant*, detainees while a handful are held in Camp 5, the maximum-security area.

Interrogation and Detainee Abuse

Compounding legal questions surrounding unlawful enemy combatants and their military tribunals, human rights organizations have criticized the treatment of detainees at GTMO. In memorandums that were not intended to be disclosed publicly, the FBI confirmed allegations of mistreatment against detainees.

It has been argued that prisoner abuse at GTMO should not be viewed apart from GTMO's overall institutional mission. From its inception, the prison was designed to provide a specialized venue where intelligence could be gathered through what the Bush administration claimed were expert interrogation methods. While in charge of the prison, Major-General Geoffrey

Miller boasted that the institution would become an interrogation battle lab in the war against terror. Under Miller's tutelage, beginning in January 2003, interrogation reportedly became more frequent and intense. Former detainees Asif Iqbal and Shafiq Rasul said they were interrogated 5 times in 2002 and never in the last half of that year; then after Miller took charge, they were harshly interrogated more than 200 times over a 15-month stretch.

Miller also revamped the prison's organization to facilitate interrogation by merging the Joint Detention Group, consisting of the guards, with the Joint Interrogation Group, comprising interrogators, translators, and analysts. As incoming guards were oriented to GTMO, they were instructed on how to coordinate prisoner treatment with the intelligence personnel, thereby fostering a culture of abuse. For instance, some have claimed that guards were led to believe that distributing privileges and punishments in living units would improve the likelihood of gathering valuable intelligence information—though such claims have been refuted. Instead, staff intensified abusive interrogation practices that would sometimes last up to 20 continuous hours. Various techniques were frequently deployed in combination: dietary manipulation, sleep deprivation (or *adjustment* to refer to reversing the sleep cycle from night to day), isolation (up to 30 days), shackling in painful positions (*stress and duress*), and exposure to extreme heat and cold as well as to loud noise/music, strobe lights, and unpleasant odors (*sensory bombardment*).

Also utilized was an array of cultural techniques intended to heighten fear among Muslim males, such as death threats aimed at them and their families, as well as forced nudity and simulated acts of sex. Another cultural tactic involved depriving Muslim detainees of their Koran or as in one widely reported incident, flushing it down a toilet. Techniques became increasingly clinical insofar as interrogators consulted with psychologists contracted by the military. As a result, interrogators resorted to the unethical use of medical information, including the detection and exploitation of anxieties (e.g., dogs, insects, cramped

dark spaces). Eventually, harsh physical and psychological techniques used at GTMO would be exported to other prisons under U.S. military and intelligence command. When Miller was transferred to Iraq, he ordered abusive interrogation methods to be implemented at the Abu Ghraib prison, which erupted into scandal in 2004.

Indefinite Detention

Although the Barack Obama administration continued to reduce the number of detainees at Guantanamo Bay, it failed to close the facility due to strong bipartisan opposition in Congress. In 2018, President Donald Trump signed an executive order to keep the prison camp open,

subjecting the remaining prisoners to indefinite detention.

HATE CRIMES

There are various ways in which hate crimes (also known as *bias crimes*) are defined. Generally, a hate crime is defined as a crime that is motivated by or in part by racial, ethnic, religious, gender, sexual orientation, or other prejudices. The Federal Bureau of Investigation defines hate crime specifically as a “criminal offense committed against a person or property motivated in whole or in part by an offender’s bias against a race, religion, disability, sexual orientation, ethnicity, gender, or gender identity.” In the United States, Washington and Oregon were the first states to pass hate crime legislation in 1981; in 2018, 45 states and the District of Columbia have hate crime statutes (Arkansas, Georgia, Indiana, South Carolina, and Wyoming do not). States vary with regard to the groups protected under hate crime laws (e.g., religion, race or ethnicity, sexual orientation), the range of crimes covered, and the penalty enhancements for offenders. This entry reviews the history of hate crimes in the United States, including pertinent legislation, and then presents relevant statistics.

History of Hate Crimes in the United States

The term *hate crime* was popularized in the 1980s due to media reports that focused on the rise of biased crimes that resulted from growing memberships in hate-based organizations such as the

Ku Klux Klan. However, hate crimes have long existed within the United States and were first investigated by the federal government during World War I.

During the Civil Rights movement of the 1960s, federal laws regarding crimes motivated by hate were grounded in federal laws regarding individual civil rights. The first federal law that differentiated crimes committed due to motivated bias from other crimes was the Civil Rights Act of 1968. This law allowed for the special prosecution of anyone who “willfully injures, intimidates or interferes with, or attempts to injure, intimidate or interfere with . . . any person because of his race, color, religion or national origin” when a victim is attempting to take part in one of six federally protected activities, such as attending school, patronizing a public place or facility, applying for employment, or acting as a juror or attempting to vote. This law directly addressed the violation of individuals’ civil rights.

In the 1980s, states began to enact hate crime statutes. These statutes vary according to the extent of protections. All state laws protect people attacked because of their race, ethnicity, or religion, but only some state laws protect people from criminal acts based on the victim’s sexual orientation, gender, disability, or gender expression.

During the 1990s, the federal government passed a series of laws that defined hate crimes and how hate crimes are counted in the United States. The 1990 Hate Crimes Statistics Act requires the Justice Department to gather data on

hate crimes from around the country, including those motivated by sexual orientation. The Hate Crimes Sentencing Enhancement Act was passed in 1994 as an amendment to the Violent Crime Control and Law Enforcement Act. The amendment required the U.S. Sentencing Commission to increase the penalties for those convicted of hate crimes.

One of the most pressing issues regarding state hate crimes laws in the United States is whether or not these enacted laws violate an individual's right to free speech. In *Wisconsin v. Mitchell*, 508 U.S. 476 (1993), the U.S. Supreme Court held that as long as laws prohibit conduct and not speech, then the law is not a violation of a person's right to free speech under the First Amendment to the U.S. Constitution and that evidence of bias or bigotry speech can be used as evidence of intent.

Expansion of Federal Hate Crime Laws

In Jasper, Texas, on June 7, 1998, James Byrd Jr. accepted a ride from three men: Shawn Berry, Lawrence Russell Brewer, and John King. The men subsequently drove Byrd to a remote road where the men beat him severely, urinated on him, and while he was still alive chained him by his ankles to their pickup truck before dragging him for approximately 1.5 miles, which led to his decapitation. They eventually dumped his torso in front of an African American church and cemetery. King and Brewer had met and become friends while serving prison sentences and joined a White supremacist gang during that time. All three men were convicted of murdering Byrd. King and Brewer were both sentenced to death and Berry received a sentence of life in prison. Brewer was executed in the Huntsville Unit on September 21, 2011.

The nature of Byrd's death was reminiscent of lynchings in the historical South. His death, subsequent law enforcement, and community response to the arrest and prosecution of the defendants were covered by print and television media and received a significant amount of federal attention. The crime resulted in an outcry for new hate crime legislation on state and national levels as well as a significant amount of research regarding contemporary hate crimes and policy analysis.

Four months after the murder of Byrd, Matthew Shepard, a University of Wyoming student,

was murdered in Laramie, Wyoming, because he was gay. Shepard had met Aaron McKinney and Russell Henderson at the Fireside Lounge. McKinney and Henderson had offered to give Shepard a ride home. They subsequently drove him to a remote part of town where they robbed, beat, and tortured Shepard. They then tied Shepard to a fence and left him to die.

Shepard was discovered 18 hours after the initial attack by a cyclist who contacted authorities. He had suffered fractures to the back of his head and lacerations over his face, head, and torso. He had severe brainstem damage, and doctors deemed his injuries too severe for them to operate. Shepard remained in a coma on life support and never regained consciousness. He died on October 12, 1998, six days after the attack.

McKinney and Henderson were arrested and initially charged with attempted murder, kidnapping, and aggravated robbery. After Shepard's death, the charge of attempted murder was changed to first-degree murder. Henderson pled guilty to murder and kidnapping on April 5, 1999, and agreed to testify against McKinney. He was sentenced to two consecutive life sentences. McKinney's trial began in October 1999. His defense attorney argued that the intent of the crime was always robbery and that Shepard's sexual orientation did not play a role in the crime. The prosecutor contended that McKinney and Henderson had pretended to be gay in order to make Shepard comfortable enough to get in the truck with them in order to rob and murder him. He argued that the murder was premeditated. A jury found McKinney guilty of felony murder but not guilty of premeditated murder. During the jury deliberations of the death penalty phase, a deal was brokered with the support of Shepard's parents, which resulted in McKinney receiving two consecutive life sentences without the possibility of parole.

Neither Byrd's nor Shepard's killers were charged with hate crimes because neither Texas nor Wyoming had passed hate crimes legislation at the time. Like the murder of Byrd, Shepard's murder received a significant amount of media attention and a call for hate crime laws on state and federal levels.

On October 28, 2009, President Barack Obama signed the Matthew Shepard and James Byrd Jr. Hate Crimes Prevention Act, which expanded

existing federal hate crime laws to apply to crimes motivated by a victim's actual or perceived gender, sexual orientation, gender identity, or disability. In addition, the act also applied to cases where the defendant, the victim, or a weapon used in the commission of the crime had traveled over state lines; or the crime had any link to or effect on interstate commerce. The act also dropped the prerequisite that the victim be engaging in a federally protected activity.

Hate Crime Statistics

The Hate Crime Statistics Act of 1990 requires the collection and reporting of hate crime data. As a result, in 1991, law enforcement agencies began reporting hate crime data to the Uniform Crime Report (UCR). In 2001, the National Crime Victimization Survey included questions regarding whether victimization was motivated by hate. In addition to the UCR and National Crime Victimization Survey, crime victimization surveys collect data regarding hate crimes from alternatives sources.

Statistics published by the UCR in 2016 indicate that there were 6,063 single-bias incidents involving 7,509 victims. This suggests that in some crimes there were multiple victims. Of the victims, 58.9% were targeted because of the offenders' race/ethnicity/ancestry bias; 21.1% were targeted because of the offenders' religious bias; 16.7% were victimized because of the offenders' sexual-orientation bias; 1.7% were targeted because of the offenders' gender identity bias; 1.0% were victimized because of the offenders' disability bias; and 0.5% were victimized because of the offenders' gender bias. With regard to the offender's race/ethnicity, the UCR reported the following: Of the 5,770 known offenders, 46.3% were European White, and 26.1% were African American. Other races accounted for the remaining known offenders: 0.8% were Asian; 0.8% were American Indian or Alaska Native; 0.1% were Native Hawaiian or Other Pacific Islander; and 7.7% were of a group of multiple races. The race was unknown for 18.1% of known offenders.

HISTORICAL ANTECEDENTS OF PSYCHOPATHY

The terms *psychopathy* and *psychopath* evoke many erroneous, or at least overstated, images in the general populace. These notions may stem in part from such popular culture venues as television and feature film productions in which psychopaths tend to be portrayed as ruthless, remorseless, and often ingenious, killers. News agencies and documentary filmmakers also may contribute to a general sense that psychopaths are heinous criminals, as it tends to be sensational acts committed by such individuals that get highlighted. This general assumption that psychopathy is intimately related to criminality has waxed and waned throughout the historical development of the concept and will be part of the discussion throughout this entry that traces the concept of psychopathy from the 18th century to more contemporary approaches to this concept. The importance of accurately understanding psychopathy rests not with the popularity of the concept in the media and entertainment industries but with its impact within the criminal justice system.

Prevalence rates for psychopathy in the general population are estimated at between 1% and 2%,

and estimates of psychopathy in prison populations are often around 30% for violent offenders and can be much higher when all offender classifications are included. Thus, while psychopathy links to criminality, as evidenced by the overrepresentations in offender populations, the crimes committed by psychopaths are not as stereotypical as portrayed in the media. If these estimates are even relatively accurate, then this population of offenders is a serious concern for criminal justice systems. An historical understanding of the concept gained through research, forensic assessment, treatment methods, criminal responsibility (i.e., the ability to understand the nature of a criminal act and that it is wrong), and recidivism perspectives can help clarify how the current understanding of psychopathy has come to be.

As an example of the relevance of psychopathy to criminal justice systems, the Canadian Criminal Code contains a verdict of *not criminally responsible on account of mental disorder*, which implies, in part, that the offender did not have the ability to understand that his or her behavior was wrong or to control his or her behavior. Following this verdict, offenders are declared not responsible for their behavior and therefore have a different outcome in the justice and correctional systems compared to offenders found criminally responsible (e.g., placed in an appropriate mental health facility rather than a prison). Currently in Canada, a diagnosis of psychopathy has not been deemed sufficient to render a verdict of not criminally responsible on account of mental disorder due to the assumption that psychopathy does not compel behavior and does not impede cognitive awareness and understanding of a person's actions and behaviors. Thus, the current conception of psychopathy assumes that psychopaths have the ability to interpret right from wrong and to control their behaviors but choose not to. The lack of empathy, guilt, and responsiveness to punishment common in many psychopaths (discussed later in this entry) therefore are not judged as sufficient pressures on behavior to remove criminal responsibility for an act.

18th- and 19th-Century Conceptions of Psychopathy

The person usually credited with the first demonstrable link to the concept of psychopathy is

Philippe Pinel, a physician and psychiatrist in France during the late 18th and early 19th centuries. Pinel was also the director of two *insane asylums* (i.e., mental institutions) and is best known as an early advocate for *moral treatment* of the mentally ill. As such, he was a proponent of a more humane treatment of patients—such as more access to personal hygiene and less use of restraints for patients—rather than the punitive and punishing treatments that had been the standard up to that point.

From his work with patients, Pinel described several cases in which patients performed violent acts toward others as well as self-harm that did not derive from psychosis. That is, the behavior occurred in the absence of delusional or manic thoughts. He dubbed this mania (insanity) without delirium (*manie sans délire*). To Pinel, this was different from other forms of insanity as it did not include a cognitive impediment, and the patients were aware of their behavior. This was counter to prevailing conceptions of insanity, which focused on mania, delusion, and low intellectual ability. Pinel further presented these cases as neutral in a moral context. That is, he did not socially condemn those with this condition as inherently immoral or evil.

A contemporary of Pinel in the United States, Benjamin Rush, had a distinctly different opinion of what is now referred to as *psychopathy* than Pinel. Rush, writing in the early 19th century, described the concept as a specific personality defect focused on the person's moral faculty rather than on a cognitive or affective issue. *Faculty* in Rush's sense derives from Scottish commonsense philosophy and refers to a psychological capacity. Rush thought that this failure to develop a proper moral faculty was due to heredity or possibly disease. Due to these factors, Rush believed that those with this condition would be more suited to commitment to a mental institution rather than a prison and opined that this condition could be treated by strengthening the moral faculty to enable more control over, and perhaps evaluation of, an individual's behavior. This focus on the moral faculty also resulted in social condemnation of psychopathy as the concept was not treated in the morally neutral stance of Pinel.

Perhaps the next influential conception of psychopathy was provided by James Cowles

Prichard, a physician in Britain, in the mid-19th century. His concept of *moral insanity* referred to personality defects related to affect and behavior rather than cognition. Prichard contended that the morally insane were well aware of the nature of their behaviors, they knew right from wrong, but the volition was not theirs. He went so far as to suggest that moral insanity could be used as a legal defense due to the compulsiveness of the behaviors. To be clear, Prichard did not employ the term *moral* in an ethical sense, although some assumed that meaning, rather he was implying an affective or emotion-based disorder. His use of the term *moral* therefore created some uncertainty and lack of clarity surrounding the concept of psychopathy in the period and may have also contributed to the increase in social condemnation of those deemed morally insane during this period.

The specific use of the term *psychopathic* began among German psychiatrists in the mid-19th century. Julius Koch introduced his concept of *psychopathic inferiority* in the late 19th century, but this was used as a broader term encompassing more personality aspects than those now associated with psychopathy. Koch did not ascribe cognitive defects to psychopathic inferiority and did not consider it to be insanity. He referred to it as a congenital defect impacting moral character but did not use the term as specifically derogatory or as a synonym for criminality as had been common in prior conceptions.

20th- and 21st-Century Conceptions of Psychopathy

In the early 20th century, Emil Kraepelin, influenced by Koch's psychopathic inferiority, introduced his concept of *psychopathic personality* with a much more restrictive definition of *psychopathic* as compared to Koch. Kraepelin focused on the darkest and most criminal aspects of personality in his conception and portrayed the psychopathic personality as morally bereft and deserving of societal condemnation. Kraepelin described several different types of psychopathic personalities with one type placing a strong link between personality aspects (e.g., self-centered, callous, irresponsible, manipulative, and deceitful) and behavior. These

personality characteristics and their strong link to behavior are still reflected in contemporary conceptions of psychopathy that will be elucidated further.

Perhaps the most influential historical conception of psychopathy was conceived by Hervey Cleckley in the mid-20th century. Cleckley, an American psychiatrist, created his conception of psychopathy through a series of clinical case studies of patients from which he derived a core of personality characteristics that are the basis for many currently held conceptions of psychopathy. Some of Cleckley's core characteristics of a psychopath include being callous, arrogant, manipulative, irresponsible, unresponsive to punishment, superficial, impulsive, antisocial, and showing a lack of remorse, guilt, or empathy. From this list, it is clear that Cleckley placed emphasis on the interpersonal and affective aspects of psychopathy and assumed that psychopaths don't respond to normal socialization processes due to some of these personality deficits. Cleckley proposed that because moral development and the development of a conscience are learned through social situations and the reinforcements and punishments present in social environments, psychopaths are unaffected by such processes. Avoiding a strict criminal perspective in describing psychopathy, Cleckley emphasized that it is not a criminal disorder but is a disorder that could put people into conflict with the legal system. He further noted that the characteristics of psychopathy could be used successfully, at least in terms of having potentially positive outcomes for some psychopaths.

One of the most notable and influential researchers and scholars in the area of psychopathy in the late 20th and early 21st centuries has been Robert Hare, most recognized for his development and validation of a widely used assessment tool, the Psychopathy Checklist-Revised (PCL-R). Hare began developing this assessment tool for psychopathy (PCL) in the 1970s, and PCL and revised versions (i.e., PCL-R, PCL-R 2nd edition) have been used widely for both research on and clinical assessment of psychopathy. Hare was influenced by Cleckley's conception of psychopathy as can be seen by the content of the PCL-R. The PCL-R consists of two factors: the first reflecting affective and

interpersonal characteristics (e.g., deceitful, superficial, manipulative, lack of guilt or empathy, and muted affect) and the second reflecting behavioral style (e.g., impulsive, parasitic, criminally versatile, and irresponsible). As with Cleckley's, Hare's conception of psychopathy is not centered on criminality; however, a person with a substantial proportion of these interpersonal and behavioral characteristics may be more prone to behaviors considered antisocial and garnering the attention of the legal system. Also in line with Cleckley, Hare does not present psychopathy as a cognitive impairment and does not assume that psychopaths are unaware of the negative societal implications of their behavior. Psychopaths seem to simply not be impacted, or at least are far less impacted, by social constraints and rules that aid in regulating behavior.

Implications for Criminal Justice Systems

The implications of psychopathy discussed are far reaching for criminal justice systems. Because psychopathy is not viewed as a cognitive incapacity and is not considered to result in compulsive (i.e., uncontrollable) behaviors, it has not been a successful legal defense as psychopaths are considered criminally responsible for their behavior. However, the lack of legal standing as a defense does not mitigate the potentially negative impact that psychopathy may pose to a criminal justice system. As noted, a substantially higher proportion of those with psychopathy find their way into the prison system than those without psychopathy. The assumption is that those with psychopathy are drastically restricted in their ability to learn from normal socialization processes (e.g., punishment). If a significant proportion of the prison population and a significant proportion of violent offenders are not amenable to current treatment options, this could negatively impact the possibility of rehabilitation, while increasing recidivism rates. Currently, the etiology of *psychopathy* is not well understood, yet a common assumption is that it is intrapersonal to a large extent. Since rehabilitation and recidivism are dependent on a more thorough understanding of the concept of psychopathy, further research is needed as the

etiology can clarify potential pathways to successful treatment.

HISTORICAL-CLINICAL-RISK MANAGEMENT-20 (HCR-20)

The HCR-20 is a commonly used violence risk assessment measure belonging to the *Structured Professional Judgment* model of violence risk assessment that sets out 20 risk factors across three scales: Historical, Clinical, and Risk Management. Violence risk assessment plays a pivotal role within criminal and forensic psychology, in

that it is used to determine the level of violence risk posed by persons typically under some form of legal supervision or incapacitation. For instance, it is commonly used at admission to, within, and discharge from prisons, forensic hospitals, and psychiatric facilities. This entry provides an overview of the HCR-20, including a brief description and history, its purpose, its applications, its core assumptions, its contents, how it was developed, how it is used in practice, and the nature of its research support.

Brief Description and History of the HCR-20

The HCR-20 is a violence risk assessment measure intended to be used by professionals who are responsible for making decisions about risk of violence posed by people typically under some form of legal supervision. The 20 risk factors are broken down across the scales as follows: Historical (10 risk factors), Clinical (5 risk factors), and Risk Management (5 risk factors). The HCR-20 User Manual details instructions for administering the measure, coding each risk factor, and making decisions about level of risk and necessary risk management strategies. The first version of the HCR-20 was published in 1995, replaced shortly thereafter with a slightly revised Version 2 in 1997. In 2013, a more substantially revised Version 3 was published. There have been 20 translations of Version 2, with 12 translations completed or underway for Version 3 as of late 2016.

The Purpose of the HCR-20

First, the HCR-20 is intended to comprehensively structure the violence risk assessment procedure from the gathering of information to the final estimate of risk level. Second, it is intended to yield summary judgments regarding a person's level of risk posed. Third, it facilitates a formulation of violence risk (an integrative, coherent explanation of a person's violence), which allows evaluators to answer the question of *why* a person has acted violently. Fourth, it leads evaluators through a systematic consideration of necessary risk management strategies required to mitigate violence risk. Ultimately, its purpose is to prevent violence.

Intended Target for HCR-20

The HCR-20 is commonly used for persons under legal supervision for whom violence risk is of some concern or must be determined as a matter of law or ethics. Some of the traditional contexts in which it is used include corrections, forensic mental health, and civil psychiatry. When a person enters any of these settings, determinations of risks posed and management needs often must be addressed. For persons residing within correctional facilities, or forensic or civil hospitals, it is used to estimate risk level, to form risk reduction plans, and to monitor risk and adjust management plans over time. It is also frequently used to inform release decisions in terms of degree of risk posed and management needs if a person were to be released into the community. It also can be used for people being supervised in the community, to establish management plans and monitor risk over time.

There are additional applications of the HCR-20. For instance, law enforcement agencies may use it as part of their work managing cases. It has been used in workplace settings as well, under occupational health and safety laws and regulations that require risk assessments to be conducted if the health and safety of employees are threatened. Clinicians in private practice may encounter situations in which a client poses a serious risk of harming third parties, and hence, they may have a legal duty to protect those third parties. Risk assessment is a vital component of this process.

Core Assumptions of the HCR-20

There are a number of assumptions that have gone into the design and implementation of the HCR-20. First, trained professionals with appropriate education and expertise, within a structured framework, can make reliable and informed decisions about risk factors, risk level, and risk management needs. Also, the majority of its risk factors are dynamic, or modifiable, and hence can serve as appropriate intervention opportunities. Additionally, the majority of its risk factors can act as causal agents of violence at the idiographic level, and hence, if they are targeted for intervention, risk will decrease. Finally, although in general the greater number of risk factors present in a

given case, the higher the risk posed, risk is not necessarily a simple linear function of the number of risk factors. Hence, professionals who use the HCR-20 are assumed to be able to exercise appropriate discretion in determining risk level through not only the consideration of the number of risk factors present, but their relevance, salience, and interrelatedness at the idiographic level. As such, decisions of high risk are permissible even with few risk factors present, as are decisions of low risk in the face of many risk factors. These assumptions have been tested and supported by research.

Contents of the HCR-20

The HCR-20 is 130-page professional manual or user guide. Chapter 1 of the user guide reviews the history and foundation of the HCR-20; situates the HCR-20 in the larger risk assessment field, including how it differs from an actuarial approach; and defines and explains key concepts, such as violence, risk, assessment, and management. Chapter 2 describes the revision process used for the development of Version 3 of the HCR-20. The third chapter includes detailed instructions on administering the HCR-20. Chapter 4 contains definitions and coding notes for each of the 20 risk factors. The Appendices of the HCR-20 contain samples of the HCR-20 Worksheets.

The risk factors are divided into three scales. The Historical Scale has 10 risk factors, denoted as a History of Problems with: (1) Violence, (2) Other Antisocial Behavior, (3) Relationships, (4) Employment, (5) Substance Use, (6) Major Mental Disorder, (7) Personality Disorder, (8) Traumatic Experiences, (9) Violent Attitudes, and (10) Treatment or Supervision Response. The Clinical Scale has 5 risk factors, denoted as Recent Problems with: (1) Insight, (2) Violent Ideation or Intent, (3) Active Symptoms of Major Mental Disorder, (4) Instability, and (5) Treatment or Supervision Response. The Risk Management Scale includes five risk factors, denoted as Future Problems with: (1) Professional Services and Plans, (2) Living Situation, (3) Personal Support, (4) Treatment or Supervision Response, and (5) Stress or Coping.

The Historical Scale captures past functioning, behaviors, and experiences. The Clinical Scale pertains to recent (past 6–12 months) affective,

cognitive, and behavioral functioning, and the Risk Management Scale refers to future adjustment and experiences in the coming 6–12 months.

Development of the HCR-20

The HCR-20 shares development principles with all Structured Professional Judgment measures. Risk factors were selected for the HCR-20 (be it Version 1, 2, or 3) based on comprehensive literature reviews and consultation with content area experts. This method is referred to as the logical or rational item selection method. It is intended to produce an evidence-based, comprehensive set of risk factors that is generalizable across settings. This method stands in contrast to how some other measures are developed, using statistical methods (such as linear or logistic regression) to extract a set of risk factors from one or (less commonly) a small number of individual samples within a particular setting. The advantage of the logical or rational item selection method is that it minimizes the possibilities that certain important risk factors will be excluded because they happened not to be significant in a given sample or were not even measured in the first place.

The development of Version 3 of the HCR-20 was based on an updated systematic literature review (including a 300-page annotated bibliography) since the publication of Version 2 in 1997. This was done to determine those risk factors that should be dropped, added, or modified.

For the Version 3 development, additional steps were taken. There was an extensive consultation process with experienced agencies and users of the HCR-20 Version 2 to seek their opinions on potential limitations of Version 2 and areas for improvement. Based on this feedback, and the experiences of the HCR-20 authors themselves, they sought to clarify ambiguities or inconsistencies; to improve the applied utility of the instrument by emphasizing individual-focused administration procedures focusing on formulation, scenario planning, and risk management; and to ensure legal acceptability by avoiding *prima facie* objectionable risk factors (such as the personal demographic attributes of gender, age, or ethnicity). Once a draft of Version 3 was developed, it was presented to an additional 30 experienced users for systematic feedback, after focus group

exercises. The draft was also beta tested in several different countries within agencies that had been using Version 2 for at least 10 years. In total, the beta testing included roughly 25 additional clinicians and the same number of evaluatees. Beta testers provided extensive feedback, and revisions to this draft were undertaken as a result.

Finally, considerable effort was devoted to the empirical evaluation of the reliability and predictive validity of the penultimate draft of the HCR-20 Version 3. This was done to ensure that the new HCR-20 would have psychometric properties at least as strong as its predecessor. Data were collected across eight sites and seven countries for the purpose of empirical evaluation of Version 3: Canada, England, Germany, the Netherlands, Norway, Sweden, and the United States. There were 782 participants (offenders and patients) included in this research, across correctional, forensic psychiatric, and civil psychiatric settings. Findings supported the reliability and validity of Version 3 of the HCR-20, and hence, it was published soon after findings from these studies became available. This development research also led to a special issue on the HCR-20 Version 3 in a 2014 issue of the *International Journal of Forensic Mental Health*.

Using the HCR-20 in Practice

The HCR-20 is intended to structure a comprehensive violence risk assessment. Users must have appropriate experience, education, and knowledge, as described in the user manual. The administration of HCR-20 Version 3 is intended to represent the natural flow of activities and decision-making that professionals undertake not only for risk assessment but also for most assessment tasks. That is, professionals must gather information, identify important and relevant facts, make sense of that information, consider the implications of the information for the future, and recommend future steps to best handle concerns. In the violence risk assessment context, evaluators gather information, assign this information to risk factors, try to make sense of why a person has acted violently in the past, consider how and under what circumstances they might act violently in the future, and recommend management strategies to reduce risk.

Because human beings generally make better decisions when the decision-making process is structured, the general decision-making process outlined above is structured into seven steps. The purpose of providing structure to the entire risk assessment (decision-making) process is to avoid, as much as possible, reliance on heuristics, bias, consideration of task-irrelevant information, and ignoring task-relevant information.

The seven administration steps of the HCR-20 Version 3 are as follows:

Step 1: Case Information

This step involves gathering and documenting enough relevant information to inform a comprehensive risk assessment. The HCR-20 Version 3 authors recommend that if at all possible the minimum information base should consist of a thorough review of case records (consisting of correctional, police, health, employment, and school files, as available) and an interview with the person of interest. Under some circumstances, information will be limited, or unavailable, in which case the evaluator must decide whether to use the HCR-20 Version 3. Where possible and indicated, other sources of information include direct observation and interviews with collateral sources such as family members, victims, or staff members who know the person well.

Step 2: Presence of Risk Factors

Each risk factor on the HCR-20 is defined within Chapter 4, and coding notes are provided. Together the definition and coding notes are used to rate whether the risk factor is present, absent, or possibly/partially present. Some of the broader or more complicated risk factors include subitems, which are optional. In addition to the definition and coding notes, each item comes with a list of indicators, which are possible ways in which the risk factor might manifest at the idiographic level. These are examples and are not meant to be coded. In addition to rating the 20 standard risk factors, evaluators can specify case-specific risk factors, so long as they can identify case facts to justify doing so.

Step 3: Relevance of Risk Factors

One of the novel features of the HCR-20 Version 3 is rating the idiographic relevance of risk factors. The 20 standard risk factors on the

HCR-20 Version 3 have support at the sample or population level. However, this does not mean that, when present, they are equally important for elevating risk of all people who have them. As such, if a risk factor is determined to be present (or possibly/partially present) at Step 2, it is treated as a hypothesis that the evaluator must explore by asking, “Is this risk factor relevant to understanding this particular person’s violence?” This step is intended to optimize the individualization of the assessment and to bridge the nomothetic and idiographic levels of analysis. It is also a mechanism for evaluators to determine what risk factors really are most important in understanding a given case.

Relevance is defined as whether a risk factor is causal at the individual level (i.e., did it drive or motivate violence, or disinhibit a person, such as violent ideation or intoxication might?), whether it impairs a person’s decision-making about violence (i.e., does it impair or destabilize careful decision-making, such as intellectual impairment or executive dysfunction might?), or whether it is otherwise critical to manage (i.e., does it allow other risk factors to persist or perpetuate, such as poor treatment plans or lack of social support might?). This process helps to answer the question *why* a person did what he or she did and to make sense of the case.

Step 4: Risk Formulation

Risk formulation furthers the process of making sense of a case. Like formulation in other contexts (i.e., therapy), risk formulation involves the application or theory or conceptual models to integrate and condense case information into a set of smaller conceptual units that explain why, in this context, a person has been violent. As such, rather than having, say, 15 risk factors to deal with, the evaluator may now have three interconnected themes that explain a person’s violent behavior. The purpose is to develop an individual theory of violence, so that we may understand why a person might be violent in the future and what we can best do to mitigate risk.

Step 5: Risk Scenarios

This step turns to the future and asks evaluators to specify plausible concerns for the future with respect to a person’s violence. If this person will be violent again, what might the person do? What might the warning signs be? Scenario planning has

been used for well over a century in other disciplines, such as military planning, and more recently for emergency preparedness, engineering, business, law enforcement, and public health. It is ideal for planning in the face of uncertainty, which aptly describes the risk assessment and management context. Typically, a small number of scenarios is specified (say, a repeat, twist, and worst-case scenario), a process that leads logically to the question, “What are we going to do to identify and manage risk under these plausible scenarios?”

Step 6: Management Strategies

This step flows naturally from the previous steps and should address the most important risk factors (present and relevant—Steps 2 and 3), why a person acts violently (Step 4), and what the person might do in the future (Step 5). Management strategies are specified under four categories: monitoring (how often, by whom, where?), supervision (how restrictive should conditions be?), treatment (what ameliorative or skills-based programming makes sense?), and victim safety planning (what can be done to help potential victims enhance their safety?). Not only should strategies be specified but so too should their details (if anger management is recommended, what specific program should it be?) and logistics (can it be ensured that the timing of this program does not conflict with other programming, or with employment?). Risk management intensity typically should be commensurate with risk level.

Step 7: Conclusory Opinions

The final step is simply for the evaluator to communicate his or her summary opinions about level of risk for which several such judgments are called. A judgment of future risk, or case prioritization, is a statement that reflects the evaluator’s opinion about the level of risk (how likely is it, based on the preceding steps, that this person will commit some form of violence in the next 6–12 months?) and concomitant degree of effort required to mitigate risk. A simple judgment of low, moderate, or high is provided. Evaluators are also asked, using the same logic, to make a risk judgment for serious (life-threatening) and imminent violence (in the coming hours, days, or weeks). These summary risk ratings have been studied extensively in research.

The Nature of Research Support for the HCR-20

The HCR-20 has been subjected to approximately 350 empirical evaluations across more than two dozen countries, the vast majority of which have been conducted by independent researchers. Most research is on Version 2, given that Version 3 was not published until 2013. Meta-analyses indicate that the HCR-20 performs at least as well as other risk assessment instruments, typically yielding moderate-to-large effect sizes. The judgments of low, moderate, or high risk have routinely been found to add incremental predictive validity to summing up the risk factors or to other risk assessment measures including actuarial ones. There has been evidence in a number of studies for dynamic predictive validity (i.e., increases in risk factors leading to increases in subsequent violence and decreases in risk factors leading to decreases in subsequent violence). Research has shown comparable predictive validity for men and women, and across countries, and settings of application.

HOMELESSNESS AND CRIME

Homelessness and crime in the United States have intertwined since at least the 17th century, when Elizabethan era poor laws regulated vagrancy through forced labor and incarceration. In a more contemporary context, a systematic examination of the intersection between homelessness and crime covers three areas. The first addresses the range of situational factors and personal characteristics that render homeless individuals more vulnerable to becoming involved with the criminal justice system. Second, homeless advocates have charged that many jurisdictions respond to homelessness by criminalizing various aspects of homeless living in an effort to drive homeless persons out of sight or out of town. Finally, just as increased risks of arrest and incarceration are endemic to being homeless, being involved in the criminal justice system and, in particular, being incarcerated increase the risk of experiencing homelessness. This entry provides a detailed overview of the relationship between homelessness and crime and examines policy approaches designed to interrupt this relationship.

Criminal Justice Involvement Among the Homeless

According to estimates by the U.S. Department of Housing and Urban Development, 564,708 people were homeless on a given night in 2015. A review by Margaret Eberle reported that, depending on the homeless population studied, between one fifth and two thirds had a criminal history. Another review, by Health Care for the Homeless, reported that between one quarter and one half of homeless populations studied had a history of incarceration, with the large majority having been jailed rather than imprisoned.

Single adults, who comprise roughly two thirds of the overall homeless population, are particularly vulnerable to interactions with the criminal justice system. As a group, single adult homeless are disproportionately poor, undereducated, male, Black and Hispanic, and have high rates of mental illness and substance dependencies. Independent of any homelessness, these groups are also more likely to become involved with the criminal justice system.

Situational factors related to being homeless create an increased vulnerability for criminal justice involvement. A lack of housing leads to more time in public spaces and to more arrests for minor offenses such as public urination or drunk and disorderly conduct. Given that homelessness, almost by definition, involves extreme poverty, homeless people will be more likely to engage in subsistence crimes such as shoplifting or trespassing when they attempt to sleep in abandoned buildings and other private property. The logistics of being homeless often lead to missed court appearances and the inability to pay tickets, citations, or other legal costs, meaning that low-level offenses escalate into warrants and to additional fines and jail time. Substance abuse, which is common among homeless persons, often involves engaging in criminal acts involving possession and distribution-related offenses. Beyond drug-related offenses, only a small proportion of the homeless milieu habitually engages in more serious criminal activity. Finally, there is drift among persons with criminal records who, as they age, typically become less criminally active but also become more vulnerable to homelessness.

Criminalization of Homelessness

Local policies, laws, and ordinances that specifically address homelessness are often the means by which homeless persons come into closer contact with the criminal justice system. This criminalization thesis (i.e., the idea that people are arrested by virtue of their homelessness) is consistent with more general frameworks that describe the control of offensive populations as a key function of law enforcement. John Irwin's *Jail* (1985) illustrates how this process applies to indigent urban populations, and classic studies of homelessness such as Egon Bittner's "The Police on Skid Row" (1967) and James Spradley's *You Owe Yourself a Drunk* (1970) illustrate how homelessness has historically been criminalized.

In a more contemporary context, jurisdictions that use ordinances to curtail certain behaviors (e.g., panhandling, sleeping in public) and restrict feeding programs for the homeless have been accused of criminalizing homelessness. Such approaches, critics contend, use a criminal justice-oriented process to remove homelessness from the public view or to harass homeless persons and prompt them to leave the jurisdiction. These measures are often the target of lawsuits against jurisdictions for infringing upon the civil liberties of the homeless and punitively addressing poverty. These legal tactics in turn are criticized for concentrating and fomenting crime among the homeless. Mike Davis illustrates this in *City of Quartz* (1990), in which Los Angeles' Skid Row serves as a proto-reservation created by a police policy to contain the homeless, thereby creating what he called "the most dangerous ten square blocks in the world" (p. 233).

Recently, the National Law Center on Homelessness and Poverty has been in the forefront of an effort to frame the criminalization of homelessness as a concerted trend rather than an aggregate of local policies. Alternately, researchers such as Eoin O'Sullivan, writing about conditions in Ireland, describe the criminal justice system as but one of an array of institutional responses that function as agents of social control in response to perceptions of homelessness as menacing, unruly, or otherwise undesirable. Some localities employ an alternative approach that takes a more social services-oriented approach to law enforcement

among the homeless. An example of this is in Washington, DC, where Jennie Simpson describes how police officers partner with homeless outreach workers to provide alternatives to arrest for getting homeless persons off of the streets.

In contrast to the widely held view of homeless persons as perpetrators of crime, less attention is given to the disproportionate degree to which homeless persons are victims of crime. While homelessness draws a disproportionate amount of police attention, this does not translate into a greater degree of personal security. Laura Huey, in *Invisible Victims* (2012), makes the most extensive examination of how homeless persons routinely are assaulted, robbed, exploited, and otherwise victimized; further, she shows the human costs related to policies that relegate destitute, powerless people, many with vulnerabilities such as disabilities, old age, and substance abuse, into the most unsafe urban areas.

Incarceration, Reentry, and Homelessness

Most research on the intersection between homelessness and crime has focused on criminal activity among those who are homeless. A smaller body of research suggests that incarcerated populations also experience disproportionately high levels of homelessness both before and after their incarcerations. Some studies have found that up to 15% of incarcerated populations were homeless in the year prior to entering jail (as compared to 1–2% of the general population). Those with a prior history of homelessness face the highest risk of homelessness upon release, but homelessness is a more general concern faced by many persons leaving jail or prison and reentering the community.

Release from prison often follows extended periods of incarceration in distant locations. This can attenuate the community and family ties that are necessary for successful reentry into the community. Poor work histories and the stigma of a criminal record make establishing economic self-sufficiency by legitimate means more difficult. In the absence of this, maintaining stable housing will require support from family, social service agencies, faith-based organizations, or other parties interested in facilitating a smooth transition for the released individual. However, many

persons return from prison to communities where these resources are underfunded and overwhelmed by demand. This sets the groundwork for a variety of undesirable outcomes to reentry from prison, including homelessness.

Persons serving longer jail sentences will have similar reentry issues as their imprisoned counterparts. However, even short-term incarcerations (the median jail stay is 1 day) disrupt lives and interfere with the ability to maintain employment and housing. Releases from jail often come as abruptly as entries into jail, involving logistics where persons are often released at odd hours and with no arrangements made for postrelease planning. This is a particular problem for persons with psychiatric disabilities, where such unplanned releases exacerbate psychiatric symptoms and complicate resuming community-based medication and treatment regimens to the point where court orders in cities such as New York have mandated more deliberate release protocols. Moreover, few jails provide more than minimal services to link those who are released to needed community services.

According to the U.S. Interagency Council on Homelessness, these circumstances lead to nearly 48,000 people who enter shelters each year coming from jails or prisons. According to prior research, 11% of a group released from prison in New York subsequently entered a shelter. Rates for homelessness among those released from jail are lower; however, more persons exiting jails will become homeless because many more people cycle through jails than prisons. More broadly, Claire Herbert and her colleagues found that, among parolees released from prison in Michigan, the number of those who were unstably housed greatly exceeded those who were literally homeless. Homelessness, in turn, increases the risk of subsequent reincarceration.

These problems with community reentry threaten to become worse as the mass incarceration trends that began in the 1970s show signs of reversing, which means that greater numbers of individuals face the prospect of being released from prison and overwhelming the sparse supply of reentry services. While it is too early to say this definitively, the looming decarceration process is a phenomenon that stands to have an impact on homelessness in a manner comparable to the

deinstitutionalization of the mentally ill that occurred in the latter part of the 20th century.

Housing, Crime, and Homelessness

Housing is the most basic response to ending homelessness, and evidence shows that, along with ending homelessness, stable housing leads to reduced numbers of arrests and incarceration (i.e., jail and prison) episodes. Among other reasons, housing reduces an indigent person's visibility to law enforcement, reduces the need for subsistence crimes, and facilitates attachment to the community. Housing, when combined with supportive services, can also help persons navigate and overcome the myriad of pitfalls that confront a person who has experienced homelessness and has an arrest record, especially if he or she has also experienced a period of incarceration.

The predominant approaches to housing homeless persons who have been in the criminal justice system are known as housing first and progressive engagement. The latter represents the traditional approach to rehousing ex-offenders, often the basis of treatment approaches by halfway houses and other similar long-term transitional facilities. Here, housing and an array of therapeutic services are provided in a highly structured environment where the participant gains increasing levels of independence as he or she progresses through the program. Alternately, the housing first approach is the model most prevalent in housing programs that target homeless individuals and involves a process whereby a person is provided immediate, independent housing arrangements and access to supportive services as he or she feels necessary. Housing first and progressive engagement represent two fundamentally different approaches, and proponents of each are often at odds with each other. Regardless of the merits endemic to each approach, there are inadequate supplies of both housing types, and such housing is most often provided in small *boutique* programs that have as of yet not been scaled to the extent required to meet demand, especially if there will be a substantial increase in the number of persons released from carceral facilities.

Beyond housing, efforts to reduce the involvement of homeless persons with the criminal justice system usually involve some measure of diversion to social services and behavioral health (including

drug treatment) systems in lieu of either arrest or the standard adjudication processes. More broadly, there have also been suits filed on behalf of homeless populations seeking to strike down laws and policies that plaintiffs argue unfairly target homeless persons.

Final Thoughts

Throughout history, homelessness and crime have been overlapping phenomena. A by-product of homelessness is an increased vulnerability to arrest and incarceration, and, conversely, insufficient levels of economic or social supports upon release from incarceration carry an increased risk of homelessness. Due to absence of any deliberate, systematic policies to either divert homeless persons from the criminal justice system or substantially increase availability of housing as a function of the criminal justice system, there is little prospect that the dynamics underlying this relationship between crime and homelessness will abate any time soon.

HOMEWORK AS TREATMENT

In a therapeutic context, homework is a request from a mental health practitioner to the client to practice a new behavior or perform a between-session task. Assigning homework is a common technique for many practitioners. Clients who complete more homework experience more positive treatment outcomes and increases in self-efficacy. Homework is an essential component within the therapy change process. Thus, increasing homework compliance is an essential task for both client and therapist.

Increasing homework compliance involves a client's perception that the homework matches the problem and goals of therapy, that it is not too difficult, and the belief that a strong relationship exists between the client and mental health practitioner. In creating such an environment, homework completion in and of itself can be considered a form of treatment. As such, within the context of criminal psychology, homework can play an

instrumental role in developing new attitudes, behaviors, and opportunities even for clients in mandated treatment. A challenge in the context of criminal justice treatment is gaining clients' trust so that they are more willing to do the homework recommended to them. Types of homework assignments are only limited by the client and counselor's creativity. Therapists can utilize a variety of categories of homework in counseling sessions in order to increase the likelihood of positive outcomes for their clients. This entry discusses positive therapy outcomes from homework, increasing homework compliance, and some types of homework.

Homework and Positive Therapy Outcomes

Homework compliance refers to the degree to which a client implements homework assignments suggested by the practitioner. Homework compliance can act as an indicator of a client's level of commitment or involvement in therapy. As such, homework compliance and treatment outcome are significantly related, suggesting that clients who comply more with homework are more likely to have better treatment outcomes. Even across different treatment populations and types of homework, the connection between greater homework compliance and better treatment outcome remains significant.

Clients who regularly complete homework realize greater degrees of improvement when compared to those who do not complete homework. Greater improvement is therefore one reason that increasing homework compliance should be a goal of a mental health practitioner, as homework may have a snowballing effect in the context of treatment. Clients who comply with homework may experience greater rates of change, making therapy more impactful, and ultimately leading to increases in their hope and motivation. This may be due in part to the fact that the client completes the homework, and so, the responsibility for improvement is in his or her own hands. In this sense, accomplishments facilitated through homework completion can be empowering for clients. Clients' self-efficacy increases through homework completion, fostering a belief in themselves because they have seen their own potential for

accomplishment outside of sessions. Thereby, homework allows a client a clear context to practice new behaviors and to develop skills learned in session before applying these behaviors or skills after termination of therapy. Discussing homework in subsequent sessions allows the practitioner and client to discuss barriers, benefits, and effects of the homework to tailor future interventions and the overall direction of treatment.

Increasing Homework Compliance

Clients who already have more buy-in to therapy may be more motivated to complete homework. However, due to the relationship between homework compliance and better treatment outcome, it is worth noting some ways to increase the likelihood that clients will complete assigned homework.

Research suggests therapists working within correctional settings may enhance clients' homework compliance by modeling desired homework tasks for clients during therapy sessions or by allowing clients to practice these tasks. This research also proposes that clients who are encouraged to commit publicly to completing assigned tasks are more likely to comply with homework. In their 2004 article reviewing homework in psychotherapy, Michael Scheel and colleagues included a model of best practices for therapist homework delivery methods.

Therapists can start by understanding that discrepancies often exist between what the therapist intends as the homework and what the client recalls as the homework. This discrepancy suggests a need to clarify homework assignments before ending a session. It is critical that the client accurately understands the homework assignment in order to appropriately and accurately complete it outside the therapy hour. This process may be especially important when working with clients within correctional settings, as it has been suggested that these clients may be more inclined to comply with homework assignments when they have a better understanding of not just the goal of the assignments but also an awareness of the potential benefits of investing time into completing assigned tasks. One way this can be done is to write out the homework assignment during session so that the client has a clear reference, similar to the way a physician writes out a prescription.

Clients may hesitate to discuss their thoughts and feelings about assignments with their therapist. Encouraging open and honest discussion about a client's thoughts concerning the homework may encourage more collaboration. This, in turn, increases the likelihood of client compliance with the homework recommendation. Collaboration is necessary because clients who perceive their therapist as using confrontation and teaching as therapy techniques (i.e., direct interventions) without including or considering the client's views may be less compliant with the recommended homework.

Along with clearly describing homework assignments and using open and collaborative approaches, the four-component model of homework acceptability should be incorporated into the process of recommending homework. First, the client must perceive a fit between his or her problems and the homework treatment. Second, the client needs to view the homework as only moderately difficult when considering factors such as time, effort, or complexity of the assigned tasks. Third, the homework should utilize some of the client's strengths. Fourth, the client needs to feel that a strong relationship exists with the therapist to engender trust in the homework the therapist suggests. Essentially, client acceptability with the prescribed homework is achieved when clients view the homework as aligned with their problem, believe that it is possible to accomplish (which includes using existing strengths to perform the task), and believe that a strong relationship exists with their therapists.

Client attitudes of acceptability with homework are associated with actually performing the homework task. Clients will complete homework that fits with their view of what they feel competent in doing (i.e., client strengths). For instance, if a client views writing as a strength, the client will be more likely to comply with journaling as a homework task. Using client strengths within homework assignments may allow clients to feel more authentic and natural, which can make tasks easier to implement.

Types of Homework

The array of available homework assignments within the context of therapy is expansive.

Therapists should collaborate with their clients to find creative homework assignments that work for a given client and relate strongly to his or her problems or goals. Homework can be passive (e.g., the client observes or experiences something), active (e.g., the client completes a task), or a combination of the two. Christopher Hay and Richard Kinnier have provided nine categories of homework in counseling.

Paradoxical Assignments

Paradoxical assignments involve assigning the symptom as the homework. The purpose of this process is to create the opposite outcome by actually taking pressure off a client who is trying to force her or his desired goal to happen too quickly (e.g., individuals identified with sexual dysfunction or sleep disorders). For instance, a client experiencing insomnia may be asked to stay up as late as he or she can. This type of homework must be used cautiously and avoided in ethically risky situations where self-harm or harm to others is possible.

Experiential and Behavioral Assignments

Experiential and behavioral assignments are specific actions that clients and therapists discuss and agree upon. These specific tasks help to change behaviors. For instance, a client who struggles with depression may be asked to engage in an activity she or he enjoys once a day (e.g., painting, walking the dog).

Risk-Taking and Shame-Attacking Assignments

Risk-taking and shame-attacking assignments are useful with clients experiencing fear. These assignments involve practicing behaviors that can help reduce a client's expectations of rejection or other consequences by acting out tasks that the client thinks would evoke the feared consequence. For instance, a client might be requested to ask a stranger on a date so he or she can experience rejection and become exposed to the fear, in essence helping to desensitize or decatastrophize.

Interpersonal Assignments

Interpersonal assignments can help with communication problems. One example would be to

have a client record both effective and ineffective interactions with people outside of session. Then the client and counselor can work together to deconstruct both the effective and ineffective ways the client communicates.

Thinking Assignments

Thinking assignments are useful to address problematic thoughts a client may possess. An example of this type of assignment is having a client write down pleasant thoughts he or she has about himself or herself. These positive self-reflections can then be referred to later when the client experiences instances of negative self-talk.

Writing Assignments

Writing assignments involve a client writing down various things, such as thoughts, feelings, goals, or behaviors. Clients can do this through journaling or writing stories and can incur a wide range of benefits from the process.

Reading, Listening, and Watching Assignments

These types of assignments are more passive in nature and allow a client to progress at his or her own pace. Examples of reading homework can be assigning the client a list of self-help books to peruse. Listening and watching assignments can involve clients observing previous sessions and paying special attention to specific topics that the client and therapist agreed upon beforehand.

Solution-Focused Assignments

Solution-focused homework assignments are directly related to a client's goal or the reduction of an identified problem. For instance, a client could have a conversation with someone he or she is in conflict with to attempt to reach a compromise.

"Don't Do Anything" Assignments

This type of assignment is useful for clients who obsess about fixing their problems. Clients gain a degree of respite from their difficulty by doing less or nothing. For instance, a client could

be asked to avoid talking about her or his problem for the week.

HOMEWORK AS TREATMENT: ACTIVE VERSUS PASSIVE HOMEWORK

Homework in therapy can be described as a task recommended to a client by a therapist to be completed between appointments, with the goal of helping the client move toward her or his treatment goal. Importantly, research has shown that the use of homework significantly improves the outcome for justice-involved individuals. Homework may be assigned to a client for a variety of

reasons, including practicing a new skill, exploring an area of the client's life, gaining knowledge on a subject, or monitoring progress. These assignments can be beneficial to clients by encouraging them to integrate therapeutic goals with their outside lives.

Several factors may influence completion and success of homework assignments. Assigning homework is often most successful when there is a strong therapeutic alliance, the client believes the assignment is a reasonable approach to her or his problem, utilizes her or his strengths, appears doable, and will be beneficial. Homework tasks can be either active or passive in nature or a combination of both. Some therapists such as those who utilize cognitive behavioral therapy use homework assignments frequently as an integral part of treatment, whereas others may use homework as a technique variably or as needed. This entry briefly distinguishes the differences between active and passive homework and provides relevant examples of how each type of homework assignment may be used in treatment.

Active Homework

Overview

Active homework is an assignment given to a client to complete a task that involves the client's participation or action. Active homework requires the client to do rather than simply observe or experience. Examples of active homework include beginning a conversation with another person, journaling when experiencing stress, maintaining a self-talk log, or incorporating exercise into their weekly routine. Some therapies that frequently utilize active homework strategies include cognitive behavioral and prolonged exposure therapies. Cognitive behavioral therapies commonly utilize client worksheets as active homework. Prolonged exposure techniques may also require active homework assignments, such as participation in anxiety-inducing events. Although active homework is commonly associated with these therapies, a variety of treatment approaches find the assignments helpful.

Example

A therapist is working with Sara, who is experiencing symptomatology of anxiety such as

racing thoughts, increased heart rate, and shortness of breath. The therapist asks Sara to describe these physiological symptoms in session. Next, the therapist provides Sara with information on the relationship between psychological distress and physiological arousal and suggests efforts to manage these symptoms through mindful breathing. The therapist introduces and demonstrates the technique of mindful breathing. Together in session, they practice the technique. Subsequently, Sara reports feeling more calm and in control of her anxiety symptoms after practicing this new skill. The therapist recommends that Sara practice mindful breathing to continue managing her physiological experience of anxiety until they meet again the following week. Two days after her appointment, Sara is on her way to work; when she remembers that she has an important meeting with her boss, she begins to experience racing thoughts, increased heart rate, and shortness of breath. Sara recognizes these symptoms as being indicators of anxiety and begins to take slow, deep, mindful breaths. Sara is engaging in active homework by practicing her new skill outside of the therapeutic context as was recommended by her therapist.

Passive Homework

Overview

Passive homework assignments often do not require clients to initiate an action or behavioral change, rather individuals are asked to complete an assignment that involves their passive participation. Often, these activities involve the client receiving information or instruction from another source. For example, a client may be asked to view a TED talk, listen to a mindfulness meditation, or read an article or book. Another form of a passive homework assignment is when the therapist recommends the client observe him- or herself or another. Observation is a common form of passive homework. As an assignment, a therapist may recommend that a client pay close attention to her or his own feelings or emotions, nonverbal communications (e.g., body language, gestures, facial expressions), or overt communications expressed by self or others. Passive homework instead of active homework may

be more suitable for clients who are not yet fully committed to therapy. Steve DeShazer recommends passive homework (i.e., observation tasks) to clients labeled *visitors* and active homework to clients labeled *customers*.

Example

Levi is struggling to communicate with his 14-year-old son, Max. He reported to his therapist that the two are in constant dispute and at times Levi believes Max “will do anything possible to begin a fight.” Levi shares with the therapist that Max has recently transferred schools and believes this may be contributing to his irritability. Levi desires a healthy relationship with his son; however, he is also busy due to stress from work. He tells his therapist that at times it can be hard to control his reactions. The therapist suggests that Levi observe his son’s behavior and demeanor upon arriving home from school each day in order to better understand Max’s mood. That night Levi noticed that Max entered the house loudly when he arrived home from school. While searching for snacks, Max would slam cupboard doors and when his pet dog came to greet him, Max looked away. Levi was able to use his passive homework assignment to gain observational information about his son’s behavior and process potential hypotheses for his son’s behavior in therapy.

Passive Versus Active Homework

Active and passive homework assignments can be difficult to distinguish, as they both involve asking the client to complete an activity outside of the therapeutic context. At times, a therapist may recommend an assignment that contains both passive and active components—for example, asking a client to observe her or his child’s behavior (passive) and react calmly (active). In short, active homework assignments require more behavioral effort than passive assignments because the nature of the assignment usually requires the individual to interact or alter her or his environment. In passive assignments, the tasks are generally more focused on increasing awareness, insight, or knowledge through observation. Despite the distinctions categorically, both active and passive homework can be useful when assigned with the

intention to help the client work toward her or his therapeutic goal.

HOMEWORK COMPLIANCE STRATEGIES

Homework assignment is considered to be a pivotal component of certain types of psychological treatments, such as behavioral and cognitive behavioral therapies. Within these types of psychotherapies, therapists assign activities to be conducted between sessions that are tailored to the client's specific problem and have beneficial therapeutic effect if complied. Numerous studies have shown that homework compliance leads to better treatment outcomes.

This entry is structured in four parts. The first section explains why homework is an important component of treatment. The second and third sections review strategies that have been shown to enhance compliance to homework in clinical settings in general as well as correctional psychotherapy more specifically. The final section explains how incentives could be used as an effective strategy to increase compliance to homework.

Why Homework Is Important in Psychological Treatments

Studies have shown that there is a relationship between positive clinical outcomes and homework activities. Psychological treatments combined with homework assignment are more effective than those without. Homework is important because it maximizes available treatment time, allows patients to practice and master skills outside the therapy, and permits patients to generalize the skills or therapeutic gains to other settings and for a period of time that goes beyond the end of treatment. These positive clinical outcomes may be even more important when the treatment involves offenders, and incarcerated offenders in particular, because treatment outcomes must generalize to the offender's lives outside the prison.

Positive treatment outcomes have also been reported in the correctional psychotherapy literature. Correctional therapies that incorporate homework have been shown to produce better outcomes in terms of reducing the severity of psychological symptoms and criminal recidivism relative to psychotherapy without homework. The problem, nevertheless, is that the positive therapeutic effects of homework exercises depend on patients' engagement with these activities. Therefore, to improve treatment outcomes, it is crucial that practitioners also incorporate strategies that enhance homework compliance. The following section describes some of these strategies.

Strategies to Enhance Homework Compliance in Correctional Psychotherapy

When assigning homework, therapists should be as clear as possible about how the activity should be performed by the client and should provide a rationale about how the homework activity is important to achieve treatment goals. It is also important that therapists discuss with the client possible challenges that they may encounter when trying to complete the activity and ways to circumvent these challenges. In addition, therapists should provide choices of homework activities and practice the assignment in session. Because written instructions have been found to increase compliance, therapists should also provide clients with a note describing the activity. Furthermore, therapists should ask about the homework

experience and summarize the activity at the beginning of the following session. While doing so, it is imperative that therapists verbally reinforce all pro-homework completion behavior.

Many of these strategies mentioned in the preceding paragraph have not been evaluated in correctional population samples. In fact, the literature on homework compliance in correctional population is scarce. One of the few studies that have investigated strategies to enhance compliance in correctional populations investigated the efficacy of three homework compliance strategies: task option, modeling, and public commitment. The first strategy involved permitting patients to choose between different homework tasks. The second involved the therapists demonstrating the correct manner to complete the activity during the session. And the third involved encouraging patients to commit with the activities publicly. Overall, the results obtained in this study indicate that task modeling and public commitment are effective strategies to enhance compliance in offender population, but further studies are warranted.

Incentive-Based Approach

As noted earlier, reinforcement is an important strategy to promote compliance. In addition to social reinforcement, therapists could provide tangible reinforcement to increase the frequency of homework completion. A large number of studies have been published since the 1980s showing that incentive-based interventions are efficacious to treat clinical conditions. These incentive-based interventions, also known as *contingency management*, are based on operant conditioning principles. In this approach, tangible reinforcers are provided contingent upon the objective verification of the target behavior.

Contingency management has been widely implemented among persons with substance abuse problems. In this treatment, patients receive incentives or vouchers exchangeable for goods and services every time abstinence from drugs is objectively verified. More recently, however, this approach has been implemented effectively in other behavioral targets, including compliance with medication, attendance at group meetings, diabetes self-monitoring, and engagement in physical activity and weight loss programs.

A few studies have used incentives to reinforce homework weekly activities in combination with incentives for drug abstinence. Although rates of compliance have not been reported, the results showed that patients receiving incentives for abstinence and homework completion achieved better end-of-treatment outcomes compared to patients who did not receive incentives. Incentive-based interventions have not been implemented in a population comprised entirely of offenders, but this approach will likely be effective in this population because a substantial proportion of substance abusers receiving treatment in community-based drug treatment are involved with the criminal justice system.

HOMICIDE

The definition of homicide is widely accepted as being the killing of a person by the consequence of another person's actions. Homicide can be a criminal act, holding the highest degree of consequences as punishable by law. Conversely, homicide can be excusable, or justifiable, by law dependent on key information such as circumstance, manner of death, and the absence of homicidal intention. The classification of homicide, investigative procedures involved in determining the classification of homicide, the application of homicide to law, statistics and prevalence of homicide, and homicide's relationship with psychology are each relevant to the conceptual understanding of this behavior.

Classification of Homicide

The legal classifications of homicide are dependent on state, province, and country of the offense. Generally, homicide is categorized into three separate types: justifiable homicide, manslaughter, and different levels of murder. Each of these types is classified based on a thorough investigative process of the event through a scope of individual circumstances.

Justifiable homicide is a classification of homicide that does not hold any criminal charge because it has been determined that no crime has been committed in the absence of *mens rea* (i.e., the knowledge of wrongdoing or criminal intention). This type of homicide is most commonly associated with the legal defense of self-defense in which an individual acts to defend himself or herself from a violent attack that results in the death of another (the attacker). In addition, justifiable homicide is extended to include the killing of a felon by a peace officer. This can also include the killing of a criminal perpetrator by a civilian if the crime was in commission at the time of the killing.

Manslaughter, however, occurs when the accused had not directly intended for the death of the victim although his or her actions had resulted in the death of the victim and his or her actions should have been foreseen as potentially leading to the victim's death. For example, manslaughter might be determined in cases in which a drunk

driver killed another driver, passenger, or pedestrian or in which a parent had left a small child in a vehicle on a hot day and the child died. This type of homicide, upon investigation, carries a sentence (unlike justifiable homicide) but typically is considerably less than that of a murder charge.

The categorical classification of murder is one in which the accused had deliberately, and with intent, killed another human. Although the classification of murder often holds subcategories as seen in some countries of residence (such as first and second degrees of murder), the concept remains that the killing was intentional but can vary in severity depending on the degree of planning.

Mens rea, specifically, refers to the mental component associated with murder (in combination with the criminal action, or *actus reus*, required for a crime to have occurred). A defining trait among homicides is related to both manslaughter and justifiable homicide, which are the reduced or element of *mens rea*, respectively. The classification of homicide is integral to the understanding of homicide in terms of culpability and potential judicial ramifications.

Investigative Procedures

To determine the appropriate classification of homicide, a thorough police investigation and sometimes ensuing legal trial are conducted. By collecting and analyzing evidence and interviewing potential witnesses and the alleged, the police attempt to reconstruct the event to determine the appropriate classification to bring forward to the courts. Forensic scientists utilize a combination of technologies to assess crime scenes and evidence that a homicide may have occurred. In homicide cases, forensic scientists are responsible for addressing the elemental questions required to classify the event as a homicide and the salient issues relating to the circumstances of death (e.g., the victim's time of death, the victim's cause of death, the potential perpetrator). Forensic scientists have been integral in the development of new technologies to aid in responding to these questions accordingly.

Forensic scientists comprise a spectrum of specializations ranging from blood spatter analysis to trace evidence analysis (e.g., fingerprints, fiber and

hair analysis, DNA analysis, impression analysis) to motor vehicle crash investigation and reconstruction. These professionals, along with forensic pathologists who attempt to determine official causes of death, are often relied upon in combination to determine whether a crime occurred and, if so, the nature of the crime.

Forensic specialists are often an extension of police enforcement agencies (sometimes a division within police enforcement agencies) but can also operate as an external resource that is contacted when there is a crime requiring their expertise.

Global Prevalence of Homicide

The United Nations Office on Drugs and Crime compiles a statistical database of global homicide data using the recently collected homicide data by the country of origin. When looking at global rates and the disparity in prevalence rates, one needs to first recognize potential causes in the differentiation. On a global scale, various nations carry a host of systemic factors that influence the rates of official intentional and nonintentional homicide. In countries that have few vehicular laws, or vehicular laws that are poorly enforced, there may be a greater incidence of manslaughter as driving under the influence of alcohol may be more common. Intentional homicide, or murder, is often a composite of influential factors based on the region of interest. Motivators of intentional homicide can be products of comorbid crime, interpersonal influences, and/or sociopolitical influences. Regions of chaotic political matters, areas of heightened alcohol and illicit substance abuse, creation and distribution, and a general lack of law enforcement can all contribute to variation in the incidence of homicide. Interpersonal influences of intentional homicide can be more prevalent in regions where there is a greater gender inequality or greater rates of domestic abuse.

Looking specifically at intentional homicide in a global perspective, there is a large gender disparity among those committing and being the victims of murder. Analyzing the global percentage distribution in 2011, the United Nations Office on Drugs and Crime reported that 95% of all accused of homicide were male and 79% of victims of homicide were also male. Although the percentage

of male and female homicide victims and perpetrators can be analyzed by the country or territory of origin, the trend in male-dominated victims and perpetrators is clear. This means that, on a global scale, males were far more likely to commit murder and be murdered.

With respect to the manner of death, or the mechanism of intentional homicide, approximately 66% of intentional homicides in the Americas in 2012 were firearm-related. This mechanism of intentional homicide was higher in the Americas than in all other geographical regions studied (Oceania, Europe, Africa, and Asia). When mechanisms of intentional homicide were globally amalgamated, firearm-related murders comprised 44% of the global mechanism of those around the world.

Homicide and the Law

The legal procedures and consequences to manslaughter and murder vary greatly around the world. It is difficult to characterize the ramifications of manslaughter or homicide on an international scale as there is not one judicial system that is adopted universally. Although a great variation exists, each event should be analyzed without bias to determine the guilt of the individual. The individual who may have committed the crime, be it murder or manslaughter, may be referred to as the accused. The accused is then tried in a court system in which the event that resulted in the death of the other person is assessed through collected evidence. Evidence may be a combination of physical trace evidence (e.g., DNA, a possible weapon, fingerprints) and/or circumstantial evidence (e.g., theory of motivations, witness accounts). In principle, the evidence should be used in a manner that supports either the guilt or the innocence of the accused with interest in assessing the likelihood that a crime existed and that the accused was criminally responsible for the death of the other person.

This is typically demonstrated by having two parties present in an adversarial court system: one party who defends the individual being accused of a crime, supporting their innocence, and the other party who represents the judicial system and presents evidence in a manner that proves the accused's guilt. Dependent on the

country of origin, a judge may determine the guilt once the accused's case is demonstrated through both sides, or a jury, which comprises a body of citizens, may be used to establish a verdict. Oftentimes, the accused is able to choose the manner by which he or she is tried in court, which is typically a decision based on whether or not the accused believes he or she will be found innocent (i.e., a greater likelihood to be found innocent by trial of judge or by trial of jury).

Upon the determination of guilt, the accused is then bound by law to receive punishment for his or her actions that is proportionate to the crime he or she has committed. Punishment can vary by country, the classification of murder or manslaughter, and the severity of the crime. There is a wide range of potential punishments, from an imprisonment period determined by the judge to the death penalty. Although eradicated in many nations, some countries, including China, Yemen, Iran, North Korea, and the United States, still exercise the death penalty. In 2018, the death penalty was legal in 31 of the 50 states in the United States. As demonstrated in the United States, judicial system procedures and sentencing can vary not only between countries but also within a country itself.

Application of Psychology to Homicide

A prime factor in assessing culpability of an individual accused of manslaughter or murder is by determining the individual's motivations. This builds a legal case against an accused not only to support his or her guilt but also to determine the nature of the crime that has been committed. One application of forensic psychology, a division within the psychological scientific community, applies psychological theory in the assessment of individuals accused of a variety of crimes to discern their motivations and the mental state at the time of the offense. In addition, forensic psychologists attempt to determine any underlying mental disorders that may have influenced their actions. Paramount to this, a forensic psychologist is able to assess the type of help a person should receive or what their sentencing should entail (e.g., sentencing to a forensic psychiatric hospital in lieu of a prison).

Motivations for murder are diverse and can range from highly premeditated motivations to sexual or revenge motivations. Other murders may be considered *passionate* or *hot-blooded* whereby with only brief premeditation an accused kills another person (e.g., in response to an insult or perceived slight) or in cases where a person discovers his or her intimate partner in the act of having an affair. Although these are not defenses to murder, they can contribute to motivations for murder and can greatly influence legal culpability and punishment. Sometimes, psychotic phenomena (e.g., delusions, command hallucinations) can lead an individual to commit a murderous act, and the act is not known to be morally wrong (leading to an acquittal due to insanity). Thus, when a murder is committed, there is a requirement to assess an accused psychologically to determine the extent of his or her psychological capacity to formulate intention.

A popularized but controversial (empirical research in this area has led to mixed and sometimes negative findings in terms of success rate) application of forensic psychology used in murder investigations is criminal profiling. By analyzing and linking the suspected related crime scene and method of killing, or *modus operandi*, forensic psychologists or other trained law enforcement professionals may attempt to infer certain demographic, occupational, and psychological features of the individual who may have committed a crime. Forensic psychologists may also contribute to murder investigations by advising police in empirically supported interrogation practices.

HOSTAGE NEGOTIATION

Negotiation is the process of resolving conflict through discussion, and a hostage incident is one in which an individual uses force or the threat of force to take people captive against their will and hold them in order to bargain for the fulfillment of certain demands. Law enforcement engages in hostage negotiation in an attempt to influence and control the hostage taker's behavior. The value of such negotiations in saving lives has been demonstrated repeatedly. In fact, the data show that in high-risk crisis situations (whether hostages are present or not), negotiators are successful more than 90% of the time, and if negotiators are used, there are no injuries or fatalities in almost all of these incidents.

The first law enforcement hostage negotiation team in the United States was formed by Harvey Schlossberg and Frank Boltz in the early 1970s at the New York City Police Department. The basic principles they stressed then are still relevant and used today by negotiators: (a) containment and negotiating with the hostage taker, (b) understanding the motivation and personality of the hostage taker, and (c) slowing down and using time to reduce emotions and allow for a negotiated settlement.

In only about 4% of hostage incidences in the United States do hostage negotiators respond. The vast majority of incidents that negotiators deal with are nonhostage events, such as barricaded subjects (with or without victims, e.g., someone known to the subject) and high-risk suicide. Other situations include domestic violence incidents, prison or jail riots, high-risk or mental health warrants, and debriefing following crisis events. In these situations, the use of negotiators is crucial, as the emotions of the subject can be made worse by a confrontational law enforcement response.

This entry begins with a discussion of hostage versus crisis negotiation. It then reviews the stages

of a hostage or crisis incident. The entry concludes with a look at the skills negotiators use to listen to subjects and respond to their demands.

Hostage Versus Crisis Negotiation

In all incidents, including true hostage-taking incidents, law enforcement negotiators use their negotiation and intervention skills to de-escalate and defuse the crisis experienced by the subject. Even in a true hostage situation, the subject is in crisis, so crisis intervention skills can be used. For this reason, many negotiating teams now consider themselves crisis negotiating teams rather than hostage negotiating teams. For example, a bank robber has a plan to enter and rob a bank. During the robbery, a silent alarm is sounded and the police arrive. Because the plan went awry, the robber is in crisis.

Regardless of the type of situation, the subject is in crisis. Negotiators are trained to use basic crisis intervention strategies to reestablish the subject's equilibrium and resolve the subject's immediate problem. Negotiators provide a short-term, time-limited intervention that reduces the subject's emotions and increases the subject's rationality. Even in the latter stages of a crisis incident, crisis intervention skills are still critical and necessary to help the subject keep his or her emotions under control.

Stages of an Incident

A hostage or barricade incident is a process with identifiable and predictable stages. The Precrisis Stage occurs prior to the incident when the subject's emotions are under control. For the subject, a plan is developed, and he or she prepares to implement the plan. The Crisis Stage is when the plan goes awry, something occurs to the subject to cause emotions to rise out of control (e.g., he or she may be fired, a relationship ends, police arrive to the bank robbery). Negotiators use their crisis intervention skills to help the subject regain control of his or her emotions. This is the most dangerous stage of the incident for all concerned. The Accommodation/Negotiation Stage is when the subject's emotions are once again under control and the subject is thinking rationally. The Resolution/

Surrender Stage is when the subject surrenders. Because the subject is moving into the *unknown*, this stage is the second most dangerous of an incident.

Active Listening Skills

Perhaps one of the most important, if not the most important, skill a negotiator can possess is that of communication. Many people assume that communication means the ability to talk to someone. While that is important, to the negotiator, the critical aspect of communication is the ability to actively listen. The reduction of emotions requires that the subject be allowed to vent and validate his or her emotions. For this to occur, the negotiator uses active listening skills and allows the subject to talk, demonstrating to the subject that he or she is being heard and taken seriously. The active listening skills critical to negotiations include (a) effective pauses, (b) open-ended questions, (c) paraphrasing, (d) emotional labeling, (e) minimal encouragers, (f) mirroring meaning, and (g) I-messages. For example, instead of asking the subject, "Have you and your spouse been fighting," the negotiator might use an open-ended question such as, "Can you explain what happened between you and your spouse this morning?". After the answer, the negotiator might then say, "It sounds like as your argument escalated, you became frustrated more than angry" (emotional labeling).

Demand Issues

Ultimately, subjects want something from law enforcement. To successfully resolve a hostage or crisis incident, negotiators must deal with these demand issues. Almost anything the subject asks for—with the exception of weapons, release of prisoners, trading of hostages, and drugs—is negotiable. Although negotiators are open to negotiating the subject's demands, that does not mean the subject will get what he or she asks for. The role of the negotiator is to listen to the subject, reduce the subject's emotions, and help the subject engage in problem-solving. The negotiator may work on reducing demands made; however, making decisions with regard to the demand issues is typically the responsibility

of the incident commander rather than the negotiator. With the passage of time, grandiose demands, such as asking for US\$1 million and a plane to a foreign country, often become more reasonable demands (e.g., food, water, cigarettes).

HUMAN TRAFFICKING

One of the significant issues confronting the global community in the 21st century is the increasing frequency and spread of human trafficking. The United Nations (UN) Office on Drugs and Crime as part of the UN Convention against Transnational Organized Crime defined human trafficking in the *Protocol to Prevent, Suppress and Punish Trafficking in Persons*. According to Article 3(a) of the protocol, human trafficking is the

recruitment, transportation, transfer, harbouring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation.

Included in the definition are acts of sexual exploitation, prostitution, forced labor and/or services, slavery, practices similar to slavery,

servitude, and the removal of organs (including surrogacy and ova removal). Forced marriage has also come to be considered a form of human trafficking.

Internationally, there are few countries that are not affected by human trafficking problems—whether their citizens and communities are involved in the acts of trafficking of humans or whether they use the services of humans who have been trafficked. In addition, few segments of societies, involving both adults and children, are affected by human trafficking issues in some way. Despite growing international efforts to control and reduce human trafficking, it continues to threaten the foundations of human rights. This entry further defines human trafficking and discusses various avenues for addressing it.

Human Trafficking Versus Human Smuggling

Human trafficking is not the same as human smuggling. Human smuggling, while it involves the transport of humans across transnational borders, involves victims who have given their consent to be smuggled into a country, are released upon reaching their destination, and make payment for the services rendered to smuggle them. For example, thousands of people from Central America and South America are smuggled into the United States each year.

A common scenario of human smuggling involves a victim paying a person (coyote) to get him or her across the border. Coyotes can release the victim upon payment on either side of the border. Some coyotes may release victims in Mexico and simply point north, requiring victims to find their own way. Others actually transport victims across the border. In some cases, an accomplice of the coyote will be waiting on the U.S. side of the border and transport the victims to other parts of the United States.

There can be overlap between human trafficking and human smuggling, which can blur the distinction between the two. For example, coyotes may get the victim across the border for promise of payment—and then, when in the United States, keep the victim captive and force the victim to engage in trafficking activities until payment is made in full. To keep the victim

engaged in trafficking activities, the coyote might take actions to ensure that the payment is never received in full.

Sometimes, drug trafficking organizations in Central America and South America may coerce victims into trafficking activities. A common scenario is for the drug trafficking organization to get a victim to agree to take drugs across the border and then threaten the victim or the victim's family to force them to return and take more drugs across the border. For the victim, this creates an ongoing cycle from which it is hard to escape. Smuggled migrants are particularly susceptible to being victimized and forced into trafficking activities, as many will not go to law enforcement authorities for assistance for fear of deportation.

Types of Human Trafficking

Types of human trafficking include child labor, forced labor, and bonded labor. Child labor has been reported by the International Labor Organization (ILO) to be a several billion-dollar industry involving over 152 million children (2016 data). Because of international legal and cooperative efforts, human trafficking in children has seen a slight decrease since 2000, when approximately 246 million children were trafficked. Child trafficking is most prominent in sub-Saharan Africa, Asia, and the Pacific.

Forced labor is when victims are held against their will and forced to work for the trafficker (or organization) and then turn over monies earned to the trafficker. The ILO estimated that in 2005, forced labor was a US\$3 billion global industry. By 2016, according to the ILO, it had risen to a US\$150 billion global industry and is expected to continue to rise. Victims are commonly found in the agricultural industry, construction, domestic roles, janitorial jobs, food services, service industries in general as unskilled labor, sweatshops, factory workers, and the sex industry. Some have suggested that most persons involved in the global pornography market (especially females) are victims of human trafficking.

The third category of human trafficking, bonded labor, is the grey area between trafficking and smuggling. Victims are forced to work in one of the aforementioned industries and repay their traffickers.

Other categories of human trafficking that are much less prevalent are forced marriages and organ removal. It is not uncommon for persons in developed countries who need organ transplants to travel to less developed countries to obtain the transplant. In many cases, the donor is forced.

Statistics

Because human trafficking is a global phenomenon, it is difficult to assess the number of people victimized by it. In 2016, the ILO estimated that there were 40.3 million victims of human trafficking in the world. The UN data (*Global Report on Trafficking in Persons, 2016*) estimate that there are over 244 million international migrants in the world (up from 173 million in 2000), a population prone to be victimized by human traffickers. According to the UN report, in North America alone, victims of human trafficking came from 137 different countries (and these data reflect only those victims discovered by authorities).

Almost every country of the world is in some way involved and/or affected by human trafficking, either as a country of origin, transit, or destination—or all three. In general, humans are trafficked from less developed countries to more developed countries. In less developed countries, poverty is often a trigger for the victim, who sees going to a more developed country as an opportunity; a motivation easily exploited by the traffickers. The most common form of human trafficking, according to the UN report, was sexual exploitation and prostitution (72%) and forced labor (20%) among female victims and forced labor (85.7%) and sexual exploitation (6.8%) among male victims. These results could be misleading, as sexual exploitation is the most documented because it is the most open and obvious. Trafficking crimes such as organ removal, servitude, forced marriage, and labor are much less overt. More women are victimized than men or children. In a number of cases, women victims become the trafficker as a way to escape their own victimization. For example, a woman being sexually exploited may be told that if she will help get other women involved, she will no longer be exploited.

The majority of traffickers are transnational criminal organizations (TCOs). Human trafficking is a global enterprise, with TCOs sharing

resources, logistics, personnel, and intelligence resources. TCOs that were once confined to a specific region or area of the world are expanding into worldwide markets. Just as with drugs, weapons, and money laundering, human trafficking is simply a commodity to these organizations.

Efforts to Address Human Trafficking

Efforts to reduce or eradicate human trafficking can take various approaches, including legislation, advocacy, and recommendations from the UN.

Legislation

According to the UN definition, human trafficking has three elements: the act, the means, and the purpose. The act, or what is done, includes harboring, receipt of persons, recruitment, transportation, and transfer. The means, or how it is done, includes abduction, abuse of power or vulnerability, coercion, fraud, force, and giving payments or benefits to a person in control of the victim. The purpose, or why it is done, are the specific uses of the persons, which can include forced labor, slavery or similar practices, using the victim for purposes of prostitution, and removal of organs.

As part of the definition (and in Article 5), the UN requires that states enact legislation that incorporates the elements of the definition. Because nations have different legislative systems, adopting the definition verbatim is not possible, but each nation is expected to incorporate the essential elements of the UN definition into its laws. Also expected to be criminalized are acts consisting of an attempt to commit a trafficking offense, participation as an accomplice, and organizing and/or directing others to engage in human trafficking. In addition, laws should include and differentiate trafficking across and within borders, include the range of exploitation (not just sexual), and clearly include men, women, and children. Moreover, laws should recognize and include nonorganized crime actors. However, given that the UN is an advisory body, there is no mechanism to force nations to enact and enforce such laws.

Therefore, in order to eradicate human trafficking, nations need to enact joint laws and court systems that can take stern criminal measures

against TCOs and others involved in human trafficking and not provide a sanctuary or safe haven for criminals engaged in human trafficking. Much like war crimes, nations need to develop an international standard of conduct, trial, and punishment for engaging in human trafficking.

Advocacy

In the United States, as elsewhere in the world, human trafficking is a significant problem. One of the leading advocate groups fighting human trafficking in the United States is the Polaris Project, a nonprofit volunteer group that fights human trafficking on a variety of fronts, and whose stated mission is to *eradicate modern slavery* and human trafficking. It also operates the National Human Trafficking Resource Center Hotline (1-888-373-7888) and Polaris BeFree Textline (text “BeFree,” 233733), which victims can use to receive help and assistance to escape the bondages of modern slavery. In addition to the National Human Trafficking Resource Center Hotline, Polaris operates global hotlines, has services for victims of trafficking, works with governments to introduce legislation, conducts extensive data analysis on human trafficking, and provides interventions to disrupt and stop human trafficking. Their efforts use a three-step model to disrupt and stop human trafficking: (1) respond to victims, (2) equip communities and others to prevent human trafficking, and (3) disrupt the business of trafficking using targeted campaigns.

Using limited data from the National Human Trafficking Resource Center Hotline from phone calls, e-mails, texts, and online reports, in the first-half of 2016 (January 1–June 30), the states with the highest contacts from victims were California, Texas, Florida, Ohio, New York, Michigan, Georgia, Illinois, New Jersey, and North Carolina. The most frequent contacts were for sexual exploitation (73%), forced/bonded labor (13%), and a combination of sexual exploitation and labor (3%). In terms of sexual exploitation, the top venues were hotel/motels (11%), commercial-front brothels (11%), online ads, venue unknown (5%), residential brothels (5%), and street-based contacts (1%). For labor exploitation, domestic contacts were most common (21%), followed by agriculture (11%), traveling sales crews (9%),

restaurant/food service (8%), and health and beauty services (4%).

UN Recommendations

Given the scope, complexity, severity, and extent of the problem of human trafficking, the UN recommends several efforts that may help to reduce and stop human trafficking. The first recommendation is to gather accurate and comprehensive data to gain a comprehensive picture of human trafficking. Only then can legal and educational efforts be undertaken to manage and stop human trafficking. The second recommendation is to interrupt and stop TCOs and other international criminal organizations involved in human trafficking. The next recommendation is for nations to make solving the problem of human trafficking a priority. It is easy to give human trafficking a back seat, given the myriad of problems faced by nations, especially developing nations. Many of these issues, however, help foster an atmosphere conducive to human trafficking. The fourth recommendation is for nations to undertake comprehensive programs to raise public consciousness of the problem and to prevent human trafficking at its points of origin. The fifth recommendation is to fully implement the *Convention Against Transnational Organized Crime and the Protocol to Prevent, Suppress and Punish Trafficking in Persons, Especially Women and Children* internationally. The sixth recommendation involves establishing relations between nations, especially the end countries (original and destination), as nations have to understand the symbiosis between each other and enact joint programs to make human trafficking unacceptable to all. Finally, it takes the efforts of everyone together—nations, organizations, law enforcement, and support groups—to reduce the impact of human trafficking.

IDENTITY THEFT

Identity theft involves the nonconsensual, unlawful use of another person's personally identifying information such as name, date of birth, and Social Security number. It is one of the fastest growing and pervasive crimes in the United States, and the risk of victimization continues to increase as the world becomes more dependent on technology and virtual record keeping. As businesses and consumers rely more on online banking, the use of online payment systems, and credit accounts with numerous retailers, as well as the electronic storage of documents, the chances of exposure to identity theft increase. Although identity theft is often difficult to fully assess, precautions can be taken by individuals and businesses to prevent the theft of information and/or minimize the fraudulent use of that information. The following entry focuses on estimates of identity theft in the United States, what is known about offenders and victims, and the methods offenders use to steal information and commit fraud.

Estimates of Identity Theft in the United States

Varying measures may be used to assess the extent of identity theft, thus making it difficult to provide accurate estimates of this crime. In some cases, certain types of identity theft may be reported as other crimes, such as credit card fraud, or other types of theft, such as mail fraud. Accurate numbers are

also difficult to ascertain as identity theft is likely underreported to law enforcement. For example, some victims do not know that they have been victimized (e.g., young children), and some victims report discrepancies in charges or account information to credit card companies or financial institutions capable of resolving the issues without legal intervention. Identity theft victims, unlike those of traditional theft such as purse snatching or shoplifting, may go long periods of time without realizing that they have been victimized.

To address the gap in information on identity theft victimization, the U.S. Department of Justice's National Crime Victimization Survey began collecting information in 2008. Recent data suggest that in 2014 an estimated 17.6 million persons, nearly 7% of all residents in the United States aged 16 or older, had been victims of identity theft. According to the report, the most common types of misused information were from existing bank accounts or credit card accounts.

Javelin, a research-based consulting firm, reported slightly fewer victims; however, it employs a measure of identity fraud (i.e., the fraudulent use of identifying information) and utilizes a different sampling method. Javelin estimated that roughly 13 million Americans were victims of identity fraud in 2015. According to its research, the type of identity fraud has changed since it began collecting data in 2005, with new account fraud increasing 113% from 2014 to 2015. This type of fraud occurs when perpetrators empty out accounts and forge checks using stolen identities and new bank accounts.

It is not uncommon for the identity thieves of U.S. victims to reside outside the United States. Javelin attributes this increase to the introduction of chip-enabled Europay, Mastercard, and Visa debit and credit cards in the United States. These cards have been used in other countries for many years as a method of fraud prevention. The technology requires card readers that are equipped to read the chips. Although this change made in-person fraud more difficult, a string of security breaches at a number of major retailers, including Target, Home Depot, JPMorgan Chase Bank, among others, exposed millions of employees' and customers' credit and debit card numbers as well as personal information to thieves. These data breaches made it easier for thieves to steal the personal and financial information of millions of consumers and then resell that information to a wide range of offenders who may then use it to open new accounts, garner insurance benefits, and create identification documents.

Methods of Identity Theft

Offenders use multiple methods to obtain the identities of their victims. The most basic and obvious way is through stealing information from wallets, purses, and mailboxes, using traditional methods of theft in order to achieve identity theft. Obtaining access to medical, student, employee, or bank records is another way in which information can be stolen. As these records usually contain personal information, perpetrators can use these records to commit identity theft, especially when the records contain Social Security numbers. In order to obtain these records, identity thieves may use their access at work, steal documents from the trash, or use Internet searches. The use of phishing scams, in which fake websites that mimic popular sites are used to obtain information, e-mail scams, and keystroke loggers also allow offenders to obtain information. Such information can also be purchased from companies and employees who have access to it or from criminals who have stolen it. Once enough information is obtained to apply for a credit card, a mortgage, or to open a bank account, offenders can move forward and commit identity fraud.

Criminals use personal information to obtain credit cards, open accounts, create counterfeit

checks, and obtain health benefits. Social Security numbers have increasingly been used to file fraudulent tax returns. As electronic forms of payment and banking become more popular, newer forms of identity theft and fraud also emerge. The use of credit card skimmers, card readers with fake keypads that submit information such as credit or debit card and pin numbers to offenders, has become a common warning to consumers. Computer and Internet access mean that offenders can steal information without leaving their homes, sometimes from halfway around the world. In the case of the 2013 Target security breach, hackers used malware to ensure that credit card numbers were sent to different points in the United States and Moscow. The breach originated in Russia, using the same malware that also affected Neiman Marcus in 2013. Multiple people were found to be connected with committing the breach, including a 17-year-old who helped develop the code for the malware. Once these programs are created, thieves may be able to make small changes that enable them to get into systems where new security measures and precautions have been implemented.

Identity Theft Offenders

It is difficult to present a profile of the *typical* identity thief, as the rate of arrest is relatively low. Based on the information available from a limited number of studies, it appears that identity thieves represent a variety of ages, races, and socioeconomic backgrounds. However, there are some commonalities found between the limited number of studies of identity thieves. According to data on those arrested for identity theft, most offenders fall within the mid-20s to early 40s age range and are disproportionately Black. The research is inconclusive on whether most offenders are male or female.

Some research suggests identity thieves come from all walks of life and have diverse criminal histories. That is, they are similar to persistent street thieves who are more likely to be drawn from disadvantaged socioeconomic households and have lower levels of education. But many are also similar to middle-class fraudsters (e.g., embezzlers), who are disproportionately drawn from more advantaged backgrounds and higher

levels of education. These data do not account for identity thieves outside of the United States, as those referenced in the previous sections, nor do they account for offenders who go undetected.

Identity Theft Victims

The National Crime Victimization Survey reported that as of 2014, victims are more likely to be female, Caucasian, and between the ages of 25 and 64 years. The number of older victims over the age of 65 years increased between 2012 and 2014. Households with an annual income of \$75,000 or more are more likely to be victimized as well. Most of the time, victims become aware that their accounts have been compromised after being contacted by financial institutions. This is not the case for new account fraud, which is typically discovered when another agency contacts victims, or when enough damage has been done that victims receive unpaid bills or have difficulty obtaining loans. Most victims do not know how their information is obtained or anything about the offender, although those who have multiple types of identity theft occur in one incident are more likely to know how their information was stolen, and by whom. The majority of victims of identity theft will experience a direct financial loss, especially victims of personal information fraud. Most victims report the fraud to non-law enforcement agencies and/or place fraud alerts on their credit reports. Moreover, many victims had engaged in some sort of preventive action prior to being victimized, while others, after being victimized, took precautions to prevent further victimization.

Identity Theft Policy and Prevention

Preventing identity theft takes effort on the part of citizens, the government, organizations, and companies. Laws that make identity theft more difficult to commit, or less rewarding, may deter people from committing the crime. The 1998 Identity Theft Assumption and Deterrence Act made it a federal crime to commit identity theft, while the 2004 Identity Theft and Penalty Enhancement Act created *aggravated identity theft*, which makes felony offenses committed with a fake identity punishable by a minimum of 2–5 additional

years, with acts of terrorism being punished more severely. The 2003 Fair and Accurate Credit Transactions Act created protections for consumers, providing access to free annual credit reports and changing the way that fraud is reported, prevented, sought, and remedied. It created a National Fraud Alert system and allows consumers to make reporting agencies aware if they feel they have been or will be victimized. States have implemented individual laws to further protect residents from becoming victims of identity theft.

Consumers can take small steps to attempt to shield themselves from becoming victims of identity theft. Checking website links, avoiding clicking unknown links or opening suspicious e-mails, and not entering passwords or checking sensitive files on a public connection are just some ways to protect information. Verifying that website connections are secure when paying bills online, installing antivirus protection software on personal computers, and making sure that passwords are difficult to guess are important. Furthermore, shredding documents that contain personal information is one of the simplest and key methods that individuals can take to protect themselves. Banks provide various security measures to protect customer information, and consumers can take protective actions by signing up for available alerts and by monitoring their transactions.

In regard to breaches of major corporations, there is little that can be done by consumers short of paying in cash, which may be impractical for shoppers, stores, and the economy when it comes to more expensive purchases. However, companies can protect customers by verifying that the security measures they have in place work and that breaches can be easily detected. Protecting login and credential information is also important. In the Target case, although the breach was detected early, credentials were stolen from third-party vendors, allowing the offenders to hack into the system and implement the malware. Monitoring employees' access and usage of patient, customer, and student information, and implementing ways that violations of protocol can be detected quickly can prevent identity theft and fraud from becoming a widespread issue. Requiring chips on credit and debit cards and asking for identification when customers make electronic purchases are some

simple ways that companies and organizations can protect their customers and, in turn, their profits. Identity theft affects more than just the individual victims, and prevention and protection require teamwork on the part of many entities.

IMMIGRATION AND CUSTOMS DETENTION

Since the mid-1980s, there has been a rapid international expansion in the use of immigration and customs detention. The decision to hold a person in immigration detention is generally implemented under administrative law provisions and is typically applied to irregular migrants arriving at the border of a country without valid entry documents or as a result of visa breaches or cancellations while resident

within a country. Immigration detention has grown as a major strategy in managing irregular migrants including asylum seekers who seek refugee protection on arrival or to facilitate removal following an adverse refugee status decision. In 2016, the Global Detention Project identified over 2,000 places of immigration detention across 100 countries. It has also estimated that in any single year, in excess of 1 million persons will be subject to some form of immigration or customs detention with an increasing number of persons being subject to extended periods of detention. In many nations, immigration detention is applied to families including children as well as adults. The United States records the highest number of immigration detainees, with over 400,000 individuals subject to immigration detention yearly.

The practice of immigration detention remains controversial under international human rights law with multiple findings from human rights bodies identifying the practice as amounting to arbitrary detention and conditions of detention involving cruel, inhumane, and degrading treatment. The decision to detain an individual generally occurs in response to a breach of domestic administrative provisions around migration and entry documents. Detention may not be subject to independent review or judicial appeal, and in some nations, periods of detention may last for extended periods. Within Australia, for example, where there is a policy of mandatory immigration detention for irregular migrants, including unauthorized onshore asylum seekers, some individuals have been held for in excess of 5 years within closed detention facilities. Conditions of detention have also raised international concern, with regular reports of overcrowding and inhumane and degrading conditions being made across settings. This entry focuses on the mental health of detainees.

Immigration Detention and Mental Health

In addition to concerns around human rights breaches associated with immigration detention, the mental health of subjected populations is a major concern. Irregular migrants and asylum seekers are likely to present with complex mental health needs due to prior exposure to adversity

and potentially traumatic events. The extent of mental health impairment in detained populations has been difficult to document with multiple barriers to research. Nevertheless, a growing body of research confirms high rates of mental disorder among detained populations that appears to be substantially higher than compatriot asylum seeker populations held in less restrictive community settings. There is also emerging evidence to suggest that the incidence and prevalence of mental disorder increase as the period of detention increases.

Detention of Vulnerable Populations

The administrative nature of immigration detention often results in detention provisions being applied to all categories of individuals. Of particular concern is the detention of children and other vulnerable populations. The total institutional environment of closed detention facilities appears to undermine parenting, limit the capacity to provide a rich learning and play environment, and regularly expose children to the distress of parents and other immigration detainees. Adverse outcomes for children appear to be mediated or exacerbated by the nature of a closed detention setting, compromised mental health of parents, and exposure to traumatic incidents. The evidence suggests that even short periods of detention will have adverse mental health effects on children.

Another group of concern are survivors of torture, organized violence, or conflict-related trauma held in immigration detention. Reviews of research into the traumatic experiences of asylum seekers identified an average rate of torture exposure of 30% in most populations surveyed. Exposure to torture has been identified as one of the most significant determinants of mental disorder across a large number of psychiatric epidemiological studies. Similar concern exists around the detention of individuals with complex health needs, with the overcrowded and stressed nature of many detention environments resulting in poor health-care outcomes for complex health conditions.

Provision of Mental Health Care Within Immigration Detention Facilities

The total institutional environment of closed detention facilities necessitates the provision of

comprehensive health services and the establishment of models of clinical care. In response to research documenting the high rates of mental disorder and associated psychological distress among immigration detainees, the role of mental health professionals working in immigration detention has expanded significantly. There has been considerable discussion in the literature about the clinical and ethical challenges faced by health professionals working in these settings. Health-care provision appears to be regularly undermined, with clinical recommendations ignored or compromised by operational considerations. The tight security and limited operational transparency around immigration detention compromise the development of models of clinical care. High rates of occupationally related stress injuries have also been documented among health and other detention facility personnel.

Forensic Issues in Immigration Detention

Many detainees will undergo various migration-related administrative reviews or decision-making processes such as refugee determination. The interaction between mental disorder and administrative decision processes has been documented to disadvantage asylum seekers presenting with post-traumatic stress disorder. There are a growing number of publications and procedural guidelines identifying the needs of psychologically vulnerable applicants within the refugee determination process and the need for improved use and interpretation of psychological evidence.

Advocacy and Immigration Detention

The continued expansion of immigration detention, despite a large body of evidence demonstrating adverse mental health outcomes associated with the practice, raises multiple ethical challenges for the health community. Health professionals are placed on the front line of care for immigration detainees and often pay a high personal cost by being witness to a system that undermines their patients' well-being. There is a growing consensus of the need for the health community to advocate for alternative responses to immigration matters,

particularly for vulnerable populations, but also as a general policy response.

IMPRISONMENT AND STRESS

Prison life is extremely stressful. Such stress is due to the prison situation itself, including loss of freedom, the sense of being reduced to a classification number and no longer a unique individual; disconnection from loved ones; loss of meaningful work and financial security; constant threat of physical and sexual assault; and omnipresent racism and endless rules to follow and punishments for breaking them. Prison conditions, including crowding and solitary confinement, greatly magnify the stress. In addition, inmates may have additional stressors, such as predisposing vulnerabilities and predispositions (e.g., history of serious mental illness, history of multiple traumas predating arrest). Moreover, some of the treatments available in correctional settings for stress-related medical and psychiatric infirmities are less than ideal, so inadequate treatment can be an additional stressor.

Stress can result in troubling physical symptoms for those imprisoned. For example, it is known that psychological pressure and blood pressure vary together: The greater the psychological pressure, the more the blood pressure rises (albeit, an approximate correlation). On average, over time, blood pressures rise in conditions where psychological pressure is intense. Thus,

there is a high prevalence of hypertension in prison solitary confinement units. When isolated in a very small space for nearly 24 hr each day, a prisoner's stress level rises, which over time can lead to an elevated blood pressure.

Stress, like pain, is prioritized differently depending on the status of the individual experiencing the stress. Thus, affluent individuals are more likely to seek and receive therapy for stress than are indigent persons of color. Continuing this logic into the prison situation, the lower one sits on the prevailing power hierarchy, the less attention there is to the stress one is forced to endure. Because prisoners are generally considered to be at the bottom of the hierarchy, their stress may not receive the attention equivalent to that paid to the stress of the general population. This entry discusses several stressors that can arise as a result of imprisonment.

Predispositions

There are predisposing vulnerabilities and predispositions, including the likely history of serious mental illness and the history of multiple traumas predating arrest, which can contribute to prisoners' stress. According to a 2014 report, in the United States, there are 10 times as many people with a serious mental illness in prison as there are in psychiatric hospitals. Trauma is an especially pernicious form of stress. Prisoners have more preincarceration trauma in their lives than does the average person in the community, and then incarceration brings about even more traumas. The traumas experienced in prison can serve as reenactments of past traumas or retraumatizations, resulting in additional stress.

Overcrowding

Overcrowding also contributes to prison stress. Since the mid-1970s, the prison population in the United States has multiplied 7-fold. With overcrowding, there is insufficient bed space; therefore, other areas of the correctional facility, such as gymnasiums, became impromptu dormitories, and four or six prisoners may be housed in cells built for one or two. Meanwhile, some conservative politicians and policy makers have attempted to both expand the prison population and

dismantle prison rehabilitation programs. As a consequence, rehabilitation programs are rarely expanded to fill the need. The robust literature on prison overcrowding has found that massive overcrowding, especially with relative idleness that occurs during incarceration, causes increased rates of violence, psychiatric breakdown, and suicide in the facilities.

The noise level in overcrowded prisons also contributes to prisoner stress, as does the fear of assault or sexual abuse that seems to be omnipresent in prison. The overcrowding itself is a stressor, but then the heightened violence is an additional stressor. Consider the seemingly simple issue of lines. In prisons, prisoners must form lines to talk on the phone, to buy commissary items, and to be served meals. With overcrowding, these lines grow longer, and one disgruntled prisoner, impatient at having to wait his turn, who yells at prisoners further up in the line to *move on*, can escalate the situation into a fight.

Prisoners With Serious Mental Illness

It can also be stressful for prisoners to live among other prisoners who have serious mental illness that is inadequately treated or even untreated. One prisoner in solitary confinement reported that as an additional form of punishment, correctional officers placed prisoners with untreated serious mental illness in the cells on both sides of his cell to ensure that he would not be able to carry on coherent conversations with his neighbors and would be subjected to loud noises through the nights. In the general population yard, prisoners with serious mental illness are often shunned or attacked, one reason being that they are considered unpredictable because of their bizarre behavior or irrational thoughts.

Inadequate Treatment

Medical and psychiatric treatment in jails and prisons is often inadequate, which means that treatment for stress-induced problems is difficult to attain. The mass prison building that occupied the latter decades of the 20th century was not matched by growth in correctional medical and psychiatric services. Thus, many medical and psychiatric conditions go untreated, undertreated, or

inadequately treated. Class action lawsuits in many states, and judges' rulings that inadequate medical and psychiatric treatment programs violate the Eighth Amendment to the U.S. Constitution's prohibition against cruel and unusual punishment, attest to the inadequate services. Thus, inadequate services for stress-related conditions become one more stressor.

As an example, consider a very anxious 57-year-old African American man who is scheduled to testify in a class action lawsuit challenging the poor level of medical care in that prison system. This man, who had been in an isolation cell for over 20 years, reported that he has been anxious for some time, but his chronic anxiety worsened significantly when he was consigned to long-term solitary. One night, a man in a neighboring isolation cell yelled aloud about the sharp pain in his chest. All of the prisoners on the pod heard him cry out and began screaming for officers to come and attend to the man. According to the inmates' report, officers did not come to the pod until more than an hour later; although the man with chest pain was taken to a hospital, he died of a heart attack. The anxious 57-year-old prisoner said, "I looked at that man writhing in pain, I knew he was having a heart attack, and then to see the officers take so much time to beckon medical attention, I get real worried that when I have a medical emergency nobody will help me!"

When a psychiatric breakdown occurs in prison, staff may attribute the bizarre behavior to *badness* rather than *madness*. Consequently, they may punish the prisoner for breaking the rules or deem the prisoner a *malingerer* who is manipulating symptoms to win removal from solitary confinement. However, when a prisoner becomes very anxious and agitated in an isolation cell and is promptly taken to the infirmary, where professionals attend to his symptoms, the prisoner will typically calm down. The professionals help to defuse the prisoner's stress, and the stress-induced symptoms—possibly including panic or psychotic experiences that were exacerbated by solitary confinement—tend to subside. Although some might argue that this scenario is an example of manipulation by the prisoner to get himself free of isolation, the attribution of manipulating or malingering to the prisoner, and the stigma attached to it, are additional sources of stress.

Disrespect

Prisoners commonly report that all they want is respect. One prisoner, when asked why he was in a high-security segregation cell, responded “Because they won’t give me any respect.” By *they*, the prisoner is referring to correctional officers who he stated beat him up for no cause. Many prisoners have experiences of disrespect throughout their lives, from that of a stepfather who abused them, to a teacher who told them they were stupid, to a police officer who addressed them with insulting terms while arresting them. In prison, other prisoners may challenge them to fight, as a matter of respect, and officers order them around every day. The disrespect felt by the prisoners is an additional stressor. Because there is no penological objective to disrespecting prisoners, treating them with respect could provide a more effective approach to rehabilitating them. If mutual respect between prisoners and prison staff were to be achieved, the level of stress in prisoners’ lives would likely diminish precipitously.

INCARCERATION, EFFECTS OF

The practice of incarceration has a long history and is utilized worldwide for numerous purposes ranging from public safety, detaining individuals for the purposes of judicial processes, punishment for illegal behavior, deterrence from future illegal behavior, and political leverage. In the first decade of the 21st century, the United States became the world’s leading incarcerator in the making. Consequently, this entry focuses only on the effects of incarceration in the United States during those five decades, an overview of which shows how the effects of incarceration extend well beyond those on an individual offender.

Brief History

Today’s practice of incarceration—the imprisonment of someone viewed as a threat to a community or a society by virtue of allegedly violating a law, or as punishment for being found guilty of violating or unable to comply with a law (e.g., unable to repay a debt)—started in the 18th century as the result of a prison reform movement that opposed public humiliation in the form of whippings, stocks, and hangings. The primary purposes of incarceration then were to provide a place in which prisoners’ behavior could be corrected through moral and religious instruction and to deter others from breaking the law out of fear of being imprisoned in harsh conditions. These reforms were further developed in the 19th century, and imprisonment continued to be viewed as a means for both punishment in keeping with the cultural standards of just deserts and rehabilitation. Through the mid-20th century, the United States followed these reformist trends in its sentencing and incarceration practices.

Shift in Punishment Ideology

Beginning in the early to mid-1960s, the evolution of social and racial unrest, urban civil rights and anti-Vietnam War protests that involved damage to property and increased use of illicit drugs—especially but not exclusively among African Americans—motivated President Lyndon Johnson to declare a war on crime in 1965 and led

President Richard Nixon to declare a war on crime in 1970 and a war on drugs in 1971, claiming that war on crime must be declared and won against the criminal elements that increasingly threatened our cities, our homes, and our lives, and that illicit drug use was the United States' number one public enemy.

As civil unrest and racial protests continued, these political declarations of war against crime and illicit drug use catalyzed a shift in cultural and criminal justice ideology that de-emphasized offender rehabilitation and increasingly emphasized offender punishment in the interests of public safety and social order. This shift was reinforced by a 1974 essay by sociologist Robert Martinson that claimed nothing worked to rehabilitate offenders, by the 1989 U.S. Supreme Court upholding sentencing guidelines that removed rehabilitation from serious consideration for the purposes of sentencing (*Mistretta v. United States*, 488 U.S. 361 (1989)), and by numerous presidents and legislators who supported increasingly punitive sentences for various categories of crime, especially the sale and use of illicit drugs.

Decrease of Mental Health Facilities

During this same time period, the belief that mentally ill individuals were best treated in their communities led to a national movement in the 1950s through the early 1970s to reduce the number of state-based inpatient mental health facilities. The loss of these facilities eventually resulted in hundreds of thousands of mentally ill individuals being released back to communities that did not have adequate treatment resources.

Confluence

The confluence of these social movements catalyzed what some critics believe to be a culture of punishment that supported a penal harm ideology. These changes included a significant increase in severity and lengths of sentences—especially for violations of drug and sex offender laws—such as mandatory minimum sentences, three strikes legislation, life without parole, trying children as adults and placing juveniles in adult jails and prisons, and a resurgence of interest in the death penalty. Consequently, according to the Bureau of

Justice Statistics, incarceration rates increased from 96 per 100,000 in 1970 to 500 per 100,000 by 2011, and the average prison sentence increased by 36% in just two decades. The increases in sentencing severity and incarceration rates were followed by corresponding increases in the number of incarcerated individuals from 200,000 in 1970 to 1.5 million adults in 2009 and over 2.2 million by 2014, when nearly one in 100 adults were in U.S. prisons or jails.

Among these incarcerated individuals were increasingly disproportionate numbers of minorities and mentally ill and drug-addicted individuals. For example, surveys have revealed that by 2014, the incarceration rates of Black males approximated 2,724 per 100,000 individuals compared to 465 for White males and that more than 60% of incarcerated individuals were members of a minority group or of color.

Surveys have also revealed that at least 50% of those incarcerated in today's jails and prisons have a mental health problem or cognitive disability, and over 60% have substance abuse or addiction histories. As a result, jails and prisons evolved into mental health and drug treatment facilities, the three largest being the Los Angeles County Jail, the Cook County jail, and Rikers Island.

The dynamic combinations of these factors—the increased emphasis on punishment, increasing severity of sentencing, and subsequent increases of incarceration rates that included increased percentages of minorities, mentally ill and drug-addicted individuals—resulted in systemic collateral and unintended consequences that extended beyond those affecting individual offenders.

The Effects of Incarceration on Correctional and Treatment Staff

Working in a *tough on crime* environment that stresses punitive control, regardless of one's position, creates significant emotional and physical staff stresses associated with coping with prison overcrowding, increased numbers of violent, mentally ill, and drug-addicted offenders. Epidemiological research has revealed that many corrections officers die much earlier than the national average, with a suicide rate twice as high as the national average, more than one third by

self-inflicted gunshot wounds. Burnout among treatment staff—particularly mental health services providers—has also become a significant concern. One study showed that mental health providers who treat sex offenders in prison settings experienced higher levels of emotional exhaustion and depersonalization and burnout. Many providers of mental health services have very high rates of depression, a sense of hopelessness, and suicidal ideation. These stressors often negatively affect the relationships between staff and inmates.

Effects of Incarceration on Offenders

There are both positive and negative effects of incarceration on offenders, to which offenders may respond in positive or negative ways. While incarcerated, a percentage of offenders may have the opportunity to participate in educational, skill-building, and treatment programs that may contribute to a successful reintegration in their communities following release. At the same time, the negative effects of incarceration may weigh heavily against the gains made by participating in these programs.

The rapid increase of incarcerating individuals and longer sentences initially led to the overcrowding of many jails and prisons. Overcrowding became and remains a serious challenge to many state and county jurisdictions. As jails and prisons initially struggled to meet the increasing demand for space, nonviolent, youthful, and mentally ill offenders were often housed within the same facilities as more violent and serious offenders, exposing inmates—particularly younger and mentally ill inmates—and corrections staff to increased incidents of violence, including physical assaults, rape, and murder. While efforts to avoid or reduce overcrowding have endured, the Bureau of Justice Statistics reports that as of 2014, prisons in 17 states were still operating above maximum capacity, with ranges from 110% to 150%, and approximately 10% of the population in jails and prisons have reported or experienced being sexually victimized.

In many overcrowded prisons, an increasing number of inmates formed gangs for protection and power, with a consequent need for prison security staff to attend to security needs, including

isolating dangerous inmates from potential victims. This led to the implementation of harsher punishments for violating prison rules that often involved lengthier placements in administrative and disciplinary segregation cells, increased use of physical (e.g., batons, Tasers) and chemical (e.g., pepper spray) restraints, an increase in *forced cell* entry that risked injury to both the inmate and staff, and reduced access to recreational and other prescribed program services. Eventually, supermax prisons were constructed during the 1990s in which allegedly dangerous individuals were and are kept in an austere environment and in their rooms 23 hr a day with limited social contact with staff and virtually no contact with other inmates. Studies have shown such placements have contributed to the deterioration of some inmates' mental health and difficulties adjusting to the prison environment and to their communities after release from prison.

The increasing rates of incarcerating mentally ill and drug-addicted individuals have also led to an increased need for drug and mental health treatment staff, a need that many jails and prisons are still not able to meet. Consequently, many mentally ill or drug-addicted offenders—especially those placed in disciplinary segregation for misconduct related to their mental illness—were not, and still are not, able to be properly treated given the lack of sufficient treatment staff.

Other studies have shown that nonmentally ill incarcerated offenders have also experienced changes in their mental status including becoming withdrawn, hypervigilant, depressed, suicidal, and experiencing post-traumatic stress responses. Suicide by jail inmates has remained the leading cause of death in jails since 2000, and suicide among state prison inmates is still slightly higher than the national average. These effects of incarceration necessitate the availability of sufficient numbers of treatment staff, an availability that studies have revealed is often insufficient to adequately meet the treatment needs of these offenders, and many mentally ill offenders are released back to their communities either untreated or inadequately treated.

The Effects of Incarceration on Recidivism

One measure of the deterrent impact of incarceration on offenders is the percentage of those

returned to prison for a new crime or other violation of their supervision: the recidivism rate. Over 680,000 individuals are reportedly released from state and federal prisons back into society on an annual basis. However, studies of recidivism in the United States have revealed that over 50% of those released are returned to prison within the first year and almost 79% are returned within 5 years.

Research has concluded that the inconvenience and harshness of incarceration have differing deterrent effects on different classifications of offenders. For example, incarcerating low-risk offenders slightly increased their risk of engaging in future criminal behavior, and incarcerating juveniles in adult facilities has also been shown to contribute to an increased likelihood of their engaging in criminal behavior as adults.

In contrast, incarceration of seasoned criminals appears to have little to no deterrent effect on future criminal behavior, and the increased harshness of the prison experience may actually contribute to increased criminal behavior for a small percentage of offenders. Other studies have shown that supervision after release (e.g., probation, parole supervision) did not appear to lower the likelihood of rearrest.

Other contributors to recidivism include the financial and relationship losses offenders may incur during their incarceration. Many offenders lose jobs, businesses, and family relationships while incarcerated, and offenders' court-ordered payments, such as family or spousal support obligations, continue to accrue during their incarcerations. As a consequence, many of these individuals are released from their incarceration in far greater financial debt than when they were initially incarcerated.

The Effects of Incarceration on Federal and State Budgets

The increased incarceration rates necessitated an increased need for more correctional facilities and services, security, and treatment staff—needs that necessitated greater expenditures of both state and federal tax dollars to pay for these increases. In 2010, Connie de la Vega and colleagues reported that spending on state prisons increased from US\$10 billion to more than US\$50 billion over the

past two decades. Reportedly, more than US\$60 billion is spent on U.S. prisons and jails annually, and spending to house one inmate in state prison for 1 year averages US\$45,000. These expenditure increases contributed to the evolution of a prison industrial complex that has profited from providing lesser expensive prison services to financially stressed states that include privatized jails, prisons, security, medical, and mental health services. Some of the private agencies have been criticized for providing substandard care to offenders in an effort to maximize profits.

For states that have a constitutional or legislative state mandate to balance their budgets, as government corrections expenditures increased, economic support for state-funded public education, social services, and related public assistance programs that may better contribute to a reduction in crime rates may be decreased.

The Effects of Incarceration on Society

There have been multiple effects of incarceration on U.S. society. First, the emphasis on incarceration as punishment tends to reassure the public that offenders who are caught will be properly incapacitated and punished, thus improving public safety. However, this reassurance has the propensity to deter the public from exploring whether this approach—with all the unintended consequences—actually works to significantly reduce crime.

Second, perhaps the most prevailing effect of incarceration on U.S. society has been the significant disparities of incarceration rates of minorities from those of the general population. Consequently, it is difficult to separate the effects of the U.S. criminal justice and increasingly severe incarceration practices from those of racial discrimination. Such disparities have contributed to research-supported claims of racial bias that pervades the U.S. criminal justice system that contributes to social unrest—particularly among minority and economically disadvantaged communities, with increased public safety risks during instances of civic protests.

Third, another prevailing effect of incarceration on society is the result of the shift of treating the mentally ill, cognitively disabled, and drug-addicted offenders from community-based

treatment facilities to prisons not adequately resourced to meet these needs. Consequently, many of these inmates are released back to communities that do not have adequate treatment resources. Studies have revealed that a percentage of these individuals are at greater risk of recidivating than individuals who are not mentally ill.

Fourth, there are local and national economic effects of incarceration. State and federal governments use taxpayer dollars to pay for the budgets necessary to implement legislated sanctions for criminal behavior and provide essential services for inmates. The economic effect of incarceration is the diversion of public money from other social programs that might advantage communities from which the majority of offenders originate and contribute to more effective crime management.

Fifth, for economically disadvantaged families, taking one or both parents out of the home for significant periods of time precipitates a domino effect of forcing many of these families to seek economic and social support from other government-funded social support agencies, agencies that can be negatively impacted by increasing government costs for jails and prisons, and consequently making them less accessible.

Sixth, in a prevailing culture of punishment, having been incarcerated has contributed to a social sentiment regarding the trustworthiness of individuals to be motivated to refrain from future crimes and the extent to which they deserve to be reintegrated in their communities. Consequently, offenders released from incarceration often encounter social and/or legal resistance to employment, obtaining housing, having a right to vote, access to education, and other services corrections research has identified as critical for a successful reentry into society. Such disenfranchisement contributes to an eventual return to criminal behavior, such as prostitution, selling drugs, and theft, just as a practical survival matter, that in turn contributes to persistently high recidivism rates commonly known as the *revolving door* that contributes to and maintains a punitive social sentiment.

The Effects of Incarceration on the United States

The results of the U.S. criminal justice system's punitive responses to criminal behavior have

earned the United States the reputation of being the world's leading incarcerator with rates 5–10 times those of other Western developed countries despite the lack of clear support for a significant reduction of crime. The global allegations of racial and economic bias in the U.S. criminal justice system are well documented; its sentencing practices have been characterized as *cruel and unusual* when compared to those of other countries with unintended and collateral consequences, including inadequate treatment for those who are mentally ill and drug addicted, that negatively impact offenders, their families, communities, and the U.S. economy.

Conclusion

There are multiple economic and social consequences that have evolved from the United States' emphases on punishment and incarceration. These consequences extend beyond those affecting individual offenders, and possibly undermining the primary purposes of incarceration as punishment and deterrence, and instead contribute to increased risks of public safety without a significant impact on crime rates. These unintended effects of incarceration have raised significant questions among the nation's leadership about the economic, social, racial, and criminal justice effectiveness of the United States' punitive approach to crime management.

INCARCERATION RATES, INTERNATIONAL

Incarceration rates provide extremely useful information for assessing the state of criminal justice systems and for their comparison. Incarceration rates of countries inform on the global state of imprisonment and criminal justice; below the level of nations, incarceration rates of specific populations, often ethnic minorities, signal differential treatment of social groups within the criminal justice system of a country. Incarceration rates are generally defined as the number of individuals per 100,000 of the population who are in a prison or a facility of detention attached to a criminal justice procedure in a given year or during another defined time period. They are the result of the

procedures and decisions within the criminal justice system and as such represent one of the outcomes of these processes. They represent the harsher and more severe end of the scale of criminal justice reactions and sanctions meted out to offenders, and in countries that have abolished the death penalty, imprisonment generally and life sentences specifically are the most severe sanctions that are imposed. Accordingly, incarceration rates are interpreted as a measure of the *punitiveness* prevailing in a country, its criminal justice system, and its population, and they illuminate the penal culture and political economy of social control and criminal justice in a society. This entry provides an overview of incarceration rates worldwide, examines the data used to determine those rates, and describes how vulnerable and minority individuals are represented.

Defining Incarceration Rates

As noted, incarceration rates are generally defined as the number of individuals per 100,000 of the population who are in a prison or a facility of detention attached to a criminal justice procedure in a given year or during another defined time period. The count of prisoners might be taken on a certain record date, which is more common, or alternatively as the average number of monthly or other time periods, which is less common. These are the *stock* incarceration rates (i.e., the number of prisoners held in penal institutions). In contrast, *flow* incarceration rates, or *admission rates*, indicate the number of individuals who enter a penal institution across a defined time period, usually a year. Both stock and flow data, or admission rates, might vary considerably; flow data, or admission rates, are indicative of the usage of prison sentences for a broad range of offenses and offenders, often for shorter periods of incarceration. Sweden is exemplary for high admissions and flows, and low stock data, implying that a larger number of offenders are sent to prison for shorter periods and only a few more serious offenders are kept in prison for longer periods of time.

What is defined as a *space of detention*, or more narrowly as a *prison*, varies among as well as within countries. Whether centers of detention for reeducation or establishments for work education are defined as a prison, certain types of open

prisons and halfway houses are counted among the number of prisons. Whether minors are included depends on the reporting system and the criminal justice statistics available for and in a country. The unequivocal link of such a facility of detention to a procedure of criminal justice excludes other detention facilities for illegal immigrants, or where individuals are held without any criminal procedures (e.g., in a conflict situation). Not all countries have written rules regarding whom and how they count as incarcerated in their criminal justice statistics. According to the *European Sourcebook of Crime and Criminal Justice Statistics* in 2014, in 23 of the European countries, statistics of incarceration are compiled based on rules, while for 11 no such rules are available. The United Kingdom has rules for England and Wales and Scotland but none for Northern Ireland.

However, even if these problems related to defining the population of prisoners are not completely solved and suggest caution, incarceration rates provide an indicator of criminal justice in a country for international comparisons across the globe, which equals the quality of other indicators of global performance and justice that are widely used. Its usefulness for international comparisons of criminal justice is owed to the fact that the modern prison is established in all countries of the world, and thus cross-national and cross-cultural comparisons of criminal justice can cover all global regions, different parts of global regions, and regions or federal states within a country (e.g., in the United States). As prisons are established in all levels of government and criminal justice, from local to the regional and national level, sweeping international comparisons can be combined with in-depth local studies. Even though the birth of the modern prison is dated back to the beginning of the 19th century, international and comparable imprisonment rates have only been available since the last decades of the 20th century and were at first only for a rather small number of countries. This number has continuously increased, and presently, incarceration rates are recorded for between 160 and 191 countries.

Data and Data Sources

International incarceration rates are available from a small number of sources. The United

Nations Office on Drugs and Crime provides numbers of prisoners and rates for different periods of time starting in 1970. The *European Sourcebook of Crime and Criminal Justice Statistics* covers the countries of the region and 41 members of the Council of Europe since 1990 and provides data in its five editions until 2011. Its in-depth information about the compilation of stock and flow data in the different countries can be deemed exemplary. The International Centre for Prison Studies at King's College London is well known for providing data on incarcerated populations around the world. The *World Prison Population Lists*, edited by Roy Walmsley, cover nearly 160 independent countries and dependent territories worldwide across more than two decades. These lists include both stock and flow (or admission) data. Since 2006, it has published the *World Female Imprisonment List*, and since 2008, the *World Pre-Trial/Remand Imprisonment List*, thus providing information about particularly vulnerable prison populations. The World Prison Brief edited by the International Centre for Prison Studies is a unique database that provides country information on a monthly basis, using data largely derived from governmental or other official sources. It collects data on occupancy levels in the prison system of 191 countries. Occupancy levels are calculated as a percentage of the total prison population in relation to the official capacity of the prison system, with 100% representing full capacity, and any percentage above overcrowding. Like the International Centre for Prison Studies, Penal Reform International is a nongovernmental organization; it provides information on Global Prison Trends, including the population of foreign nationals in prisons. Much of the information reported by these organizations is collected from prison visits (e.g., levels of overcrowding that considerably exceed in a number of prisons the total occupancy rate calculated for the country).

Overall incarceration rates for a country thus can only paint a general picture of the use of imprisonment by its criminal justice system; however, they do not provide information on different types of sentences or the different groups that are in prisons. Thus, as prison populations are built up and rapidly increase through longer sentences rather than by sending more offenders to prison for shorter terms, incarceration rates for life

sentences or long sentences would provide more detailed information and complement measures of punitiveness. In addition, overcrowding can hugely vary among prisons at the level of communities, states, or the national/federal prison system, as in the United States. Incarceration rates for women and for different age groups are mainly indicative of different levels of prevalence of crimes and are often available. Incarceration rates for pretrial and remand prisoners, for foreign nationals, and in particular for racial and ethnic minorities exceed general incarceration rates even in countries with low rates, and exemplify ways in which disadvantaged groups are subject to criminal justice. These more detailed data can complement total incarceration rates as indicators illuminating the punitiveness of a country in international comparative studies, and contemporary scholars of penal systems and punishment are increasingly looking for and examining closely such strong indicators of exclusion and inequality.

Vulnerable Groups and Racial/Ethnic Minorities

The present global cohort of pretrial and remand is estimated at between 2.5 and 3.5 million individuals who will presumably spend 660 million days in prison. In 55% of the countries, remand prisoners constitute between 10% and 40% of the prison population. They constitute more than 40% in half of the countries in Africa, the Americas, and South, Central, and Western Asia. In Africa as well as in Latin America, countries with the highest proportion above 70% are found, including Liberia and Bolivia, Democratic Republic of Congo, Nigeria, Haiti, Bangladesh, and Philippines. In the Americas, all but three countries exceed the level of a pretrial incarceration rate of 40 per 100,000 that applies to the majority of the countries, with 13 up to 150 and more, among them the United States. The overuse of pretrial detention is one of the major problems of global imprisonment and affects mostly the poor as well as economically and politically marginalized groups.

Incarceration rates for foreign nationals who are disproportionately represented among the prison population are indicative of the treatment

of such foreigners within and by the criminal justice system of a country. In 2014, a half million nonnationals were incarcerated in prisons across the globe. They constitute a large group of pretrial and remand prisoners, and they are particularly vulnerable to human rights violations within prison. Dutch prisons house prisoners from more than 100 countries. In Spain, as in other European countries, the proportion of foreign nationals in prisons increased by 50% between 2000 and 2013. However, for many countries, no information is available for this group.

Across the globe, incarceration rates for racial and ethnic minorities are considerably higher than for the majority of the population. The overuse of imprisonment for these groups even in countries with comparably low levels of imprisonment (e.g., the Scandinavian countries) constitutes one of the major problems of criminal justice and human rights across the globe. Incarceration rates for communities or regions where these groups are concentrated often hugely exceed the national level with detrimental impact on the social, economic, and political life of such affected communities. In some countries, racial and ethnic minorities represent more than half of the total prison population, and incarceration rates for these groups exceed the total country rate by a factor of 10 and more. Australia, New Zealand, and Canada incarcerate a disproportionate number of their indigenous populations. In 2012, the incarceration rate for Aboriginals and Torres Strait Islanders in Australia was 15 times higher than for nonindigenous groups; they accounted for 26% of the prison population, while only representing 2.5% of the population. The increase of the Australian incarceration rate between 2001 and 2014 was mainly due to an increase in the incarceration of the indigenous population. In New Zealand, 51% of the prison population were Maori, while their share of the general population was 15%. Racial and ethnic minorities are disproportionately imprisoned in Western Europe and in North America, while nearly no information is available from many countries in the global South.

The United States seems to epitomize this racial disparity by disproportionately subjecting Blacks to the criminal justice system, though the United States is by no means unique from a global perspective. In 2013, 3% all Blacks men

were in prison, amounting to an imprisonment rate of Blacks men of 2,805 per 100,000, compared to 1% of Hispanic males, or an incarceration rate of 1,134 per 100,000, and 0.5% of White males, or an incarceration rate of 466 per 100,000. While Blacks represent 12–13% of the population of the United States, their share of the 2.2 million individuals in prisons across the United States was 37%. The disproportionate representation of Blacks men becomes evident when comparing them to White males of the same age: The incarceration rate for Blacks men aged 18–19 years (1,092 per 100,000) is nearly 10 times higher than the rate for the equivalent group of White males (115 per 100,000), which is the highest discrepancy between these groups. In the age range between 25 and 39 years, when across the world incarceration rates peak, Blacks men were imprisoned at rates at least 2.5 times greater than Hispanics and 6 times greater than White males.

INCARCERATION RATES, U.S.

Rates of incarceration in U.S. prisons and jails are key statistics used to compare different jurisdictions, to assess the status of particular groups in the system, and to understand the impact of changes on correctional laws, policies, and practices. This entry addresses rates of incarceration, specifically how rates are calculated and interpreted; long-term trends in U.S. incarceration rates; rates by gender, race, and ethnicity; international rates; what causes rates to change; and policy reforms that might reduce rates of incarceration.

Rates Explained

Inmate counts can fluctuate along with the general population. To enable analysis of other system and societal factors in the number incarcerated, rates are used to standardize differences in population over time or across different states or countries. Rates are calculated by dividing the incarcerated population by the general population and multiplying by 100,000, giving a count on inmates per 100,000 residents. When examining specific subgroups of the population, such as men, women, or a particular race, the rate is calculated using only the number of residents belonging to that subgroup.

Trends Since 1925

The U.S. federal and state prison population remained relatively stable for most of the last century, dropping slightly in the 1940s and 1960s. U.S. Department of Justice data show that, beginning in the late 1970s, rates of incarceration in U.S. prisons climbed steeply upward until peaking at 506 in 2007. The rates have since dropped each

year, reaching 458 in 2015, the lowest since 1997. Nevertheless, incarceration rates remain very high. In 2015, the United States incarcerated 2,173,800 persons; one of every 114 adults was behind bars.

Gender

In the 30-year period of growth, the number of women in custody grew at a steeper rate than men. The number of women in prison in 2008 (the historic peak year) was over 9 times that in 1980 (12,250 in 1980 to 114,612 in 2008); the count of male inmates in the same period grew about 5 times (302,460 in 1980 to 1,496,370 in 2008). The rate for sentenced women was 11 in 1980 and 64 in 2015; for sentenced men, 275 in 1980 and 863 in 2015.

State and Regional Differences in Rates of Incarceration

The U.S. states vary widely in many ways that impact state incarceration rates, including geography, climate, demographics, region of the country, culture, public perception and political climate, legislation, law enforcement policy and practice, and characteristics of the judiciary.

Table 1 shows that, in 2015, the overall incarceration rate in state and federal prisons and local jails was 660. State rates ranged from under 350 for Maine, Massachusetts, Minnesota, New Hampshire, Rhode Island, and Vermont to 800 or more for Alabama, Arizona, Arkansas, Georgia, Mississippi, Louisiana, and Oklahoma. The federal rate was 60. Most criminal law is governed by the states, so the federal rate is always far lower than state rates.

Race and Ethnicity

Despite recent rate drops for all races and ethnicities, Figure 2a and b illustrates the disparities in rates among Whites, Blacks, and Hispanics in 2015. Figure 1 shows rates for those sentenced to at least 1 year in prison per 100,000 in the general population for each group. The rate for Whites was 312, for Hispanics 820, and for Blacks 1,745.

Figure 2 shows the same information as a relative rate index. To calculate relative rate index, the rate of one or more groups is divided by the rate of

a comparison group. A relative rate of 1.0 indicates the groups are equally likely to be incarcerated relative to their numbers in the population. The relative rates reported here show large disparity, with Blacks and Hispanics far more likely to be in custody than Whites. Hispanics were in prison at over 3 times the rate of Whites, and Blacks over 6 times the rate of Whites.

International Perspective

Other countries rely far less on incarceration than the United States does as a response to crime, especially for nonviolent crimes. In 2015, with only 4% of the world's population, the United States locked up nearly 21% of all of the world's prisoners. The Institute for Criminal Policy Research at the University of London reports that the United States has the highest incarceration rate of all nations on earth. (Very small countries are not comparable to the United States because of the size and complexity of their social and political systems, so the rates reported here are for nations with populations of at least 100,000.)

As shown in Figure 3, the Institute's most recent data showed the average rate was 92 in Western Europe, 105 in Africa, 139 in the Middle East, 169 in Asia, and 222 in South America. At 693, the United States incarcerates at a rate 5–18 times higher than other Western nations, such as the United Kingdom, France, Denmark, Finland, and Germany and over 20 times higher than nations with the lowest rates such as India, Mali, and the Central African Republic.

Factors That Drive Rates of Incarceration Up or Down

New Admissions and Length of Stay in Custody

Two system statistics determine the rate of incarceration: new admissions and length of stay in custody.

Admissions to jail or prison, whether for a new sentence, for a probation or parole revocation, or after arrest while awaiting trial, are the biggest drivers of custody populations and thus rates of incarceration. Reductions in admissions to custody directly reduce the number in custody and, therefore, rates of incarceration.

Table 1 Population Count and Rate of Incarceration in Federal and State Adult Prisons and Local Jails, 2015

<i>Jurisdiction</i>	<i>Total Inmates</i>	<i>Rate^a</i>	<i>Jurisdiction</i>	<i>Total Inmates</i>	<i>Rate^a</i>

^aRate of incarceration per 100,000 in general population including all ages.

Even if new admissions remain constant, if the length of time served is shortened, inmates exit custody sooner and overall counts fall. Length of time served can be reduced in two basic ways: reduced sentence length and reduced length of stay. While sentence length is the maximum time an inmate will remain incarcerated, the actual time served can be shortened through such mechanisms as parole and inmates earning credits

toward reducing time served by completing programs and avoiding problem behavior.

System and Societal Influences

Crime Rate

The number and types of crimes committed are certainly two of the factors that drive arrests, prosecutions, and incarceration, but they are often

not primary. For instance, the rise in incarceration rates that started in the 1970s had only a small correlation to a rising crime rate. Certainly, the rise of crack cocaine and corresponding shifts of policing policy and practice contributed. However, more than by criminal behavior, the 30-year growth was caused by changes in public perceptions about crime and criminals and related changes in law enforcement practices and in policies and laws governing who would be incarcerated and for how long.

Laws, Policies, and Their Interpretation

Each branch of U.S. government influences the correctional system by shaping, interpreting, and applying laws, regulations, and policies. The legislative branch makes laws that dictate which behaviors are criminal, mandate sentencing, and determine how much discretion judges and corrections officials have to alter sentences. Lawmakers also allocate funding to corrections agencies and thereby impact how long inmates remain in custody in a variety of ways. The courts, including judges, court administrators, prosecutors, and defense attorneys, adjudicate charges through trial or plea bargain, determine sentences, and review probation and parole violations. The executive branch (i.e., correctional agencies, probation and parole departments, police and sheriff departments) runs the prisons and jails and helps decide how much of a sentence is served, who receives parole and when, how behavior during incarceration impacts sentence length, and which probationers or parolees are returned to custody.

Public Perception

Perceptions about crime and corrections among the public, the press, and the government feed off one another, resulting in major swings in the response to real or perceived criminal behavior, often without much consideration of facts or research. The media of the 1970s and 1980s showed the public fearing crime and wanting a tough response to criminal activity; these sentiments were reflected in the *Tough on Crime* legislation of the time. In the 1990s and 2000s, California voters repeatedly passed propositions that increased the length of sentence for many

types of crime. Polls since the 2000s have shown a shift in public opinion—again reflected in changes to law and policy—toward alternatives to incarceration, both because they cost less and produce less recidivism than traditional time behind bars. Accordingly, Californians began to pass propositions that softened the state's response to many crimes and incarceration rates fell.

Reducing Rates of Incarceration

The communities where most inmates come from are characterized by high rates of poverty, limited educational and vocational prospects, inadequate social services, a lack of political representation, and generational cycles of violence and justice system involvement. High rates of incarceration, especially among the poor and people of color, will likely remain a problem until society finds solutions to these challenges.

In the meantime, there are correctional system reforms that can reduce mass incarceration. Sentencing reforms that reduce sentence lengths for nonviolent and nonsexual crimes can reduce rates of incarceration. A range of sanctions, including community-based alternatives to incarceration, reduce new admissions to prison and, when properly administered, are more effective at reducing recidivism than time behind bars. These sanctions are punitive but allow more system-involved men and women to remain in the community, closer to family, long-term services and programming, and better employment and education opportunities.

INEFFECTIVE REHABILITATION STRATEGIES

Despite expansive research acknowledging the importance of evidence-based practices that emphasize the need to target the known predictors of crime, many practitioners continue to implement strategies that are ineffective (i.e., produce no effect) or even potentially cause greater harm to offenders than good (i.e., increase recidivism). The term *correctional quackery*, applied to ineffective rehabilitation strategies, describes programs developed without consideration of existing knowledge of the causes of crime or of methods of other successful programs that have positively affected offender behavior. This concept suggests that agencies dismiss evidence-based practices in favor of *common sense*, personal experience, and tradition when determining how to manage offenders. Furthermore, practitioners often turn to programs that target factors unrelated to recidivism (e.g., low self-esteem, lack of creativity, and dieting). This entry reviews the characteristics of ineffective rehabilitation programs and the specific strategies that do not work to reduce reoffending.

Adherence to the Risk, Need, and Responsivity Principles

The correctional literature has established that to effectively reduce recidivism, agencies must adhere to evidence-based practices. In particular, programs should follow the Risk-Need-Responsivity model. The principles of this model identify offenders who should be targeted through treatment (risk), those individual factors that need to be targeted for change (need), and ways to best target these needs (responsivity).

Problems Associated With Targeting Low-Risk Offenders

Identifying moderate- or high-risk offenders for recidivism and in need of the greatest degree of change is a crucial first step for effective rehabilitation programs. However, agencies and programs often fail to engage in evidence-based methods that allow such identifications. Agencies may either avoid trying to measure risk altogether or use old and outdated instruments to do so. Additionally, correctional officers may override risk classifications that contradict their own judgments of an offender's risk level. Additionally, even when risk is determined, entities may still avoid targeting the appropriate types of offenders, favoring lower risk offenders. This can be counterproductive and result in unexpected adverse effects (i.e., increases in offending).

Targeting Noncriminogenic Needs

Another contributor to ineffective programming is a failure to acknowledge and implement causes of crime, instead targeting concepts unrelated to behavioral change (i.e., noncriminogenic needs). Research demonstrates that long-lasting and positive change in criminal behavior is achieved when the following factors are targeted: antisocial attitudes/beliefs, antisocial personality, antisocial peers, employment/education, substance abuse, family/social support, and leisure activities. These particular needs have been found to be highly correlated with risk of reoffending.

When these factors are not targeted, programs can create harmful, rather than positive, effects. Programs that stress fear of punishment (e.g., Scared Straight), target vague emotional problems, or improve the offenders' physical shape (e.g., boot camps) can actually increase recidivism rates. These programs tend to point to a failure to change on the offender rather than the program, which, in turn, may be used to justify a subsequently harsher punishment for the offender.

Using Noncognitive Behavioral Approaches

Research has consistently demonstrated that the best approach to reducing recidivism is through application of cognitive behavioral therapy (CBT). CBT is a therapeutic approach that

helps modify an offender's dysfunctional thoughts, emotions, and behaviors. However, there has been a tendency for practitioners to ignore this approach and, instead, rely on *common sense* practices often rooted in personal opinion about what works or traditional approaches to rehabilitation that research has demonstrated are not effective.

In general, programs that target offenders at lower risk of committing future crime, programs that fail to address factors associated with criminal behaviors (i.e., criminogenic needs), and programs that fail to implement CBT approaches can produce unfavorable outcomes. In place of the Risk-Need-Responsivity model, some agencies have been found to instead rely on ineffective punishment-oriented treatment with the belief that fear of punishment will prevent future criminal behavior (i.e., deterrence). Others have focused on vague approaches that utilize therapeutic discussion as a mechanism for change without targeting key risk factors. The next two sections discuss some of these ineffective programs.

Punishment-Oriented Approaches: Intermediate Sanctions

Following the expansion of prison populations in the 1980s, there was a desire to reduce crowding but also ensure that sufficient punishment was delivered in the community. Intermediate sanctions were developed as a way to address the concern that prison was too harsh but probation, too lenient. The most common form of this approach was intensive supervision programming (ISP).

ISP

ISP was developed under the premise that reduced caseload sizes for correctional officers would provide greater opportunity for close supervision of offenders. ISP quickly spread across the United States and parts of Canada with several forms of supervision including increased contact, confinement of offenders to their homes, curfew enforcement, random drug testing, requirement that offenders pay restitution to the victims, electronic monitoring, and the requirement that offenders pay for their supervision. The goals of the program were to increase public safety,

rehabilitate offenders, provide intermediate punishment, reduce prison crowding, and reduce costs. The assumption was that increased contact between the officer and offender would allow for closer observation and that the threat of punishment would lead to reductions in future offending (i.e., recidivism).

Evaluation studies of ISP, however, proved disappointing. While researchers found that ISP generally achieved increased levels of supervision, through measures of such activities as the number of supervision contacts and number of drug tests, they ultimately determined that ISP failed to significantly reduce recidivism. Studies analyzing participants in ISP and comparison groups found no difference in the recidivism rates. In one study evaluating the effects of ISP across 14 sites, researchers found that not one location had better rates than the comparison group. The evaluation concluded that ISP was no more effective than traditional probation or parole.

Additionally, ISP was found to produce increases in technical violations (i.e., violating rules of supervision). This was a direct result of increased surveillance that more easily detected such behaviors. Further, any behavioral changes that resulted from ISP were often short-lived. Once participants completed ISP and moved on to regular probation, it was found that they were arrested with increasing frequency. Interestingly, reductions in recidivism (e.g., 10%) were discovered when a treatment component was simultaneously introduced to participants. This finding implies that reductions in recidivism are a result of treatment rather than supervision.

Shock Incarceration/Boot Camps

Shock incarceration programs, otherwise known as *boot camps*, were developed in the 1980s and were modeled after military-style programming. Boot camps promised to not just watch offenders but change them through military discipline. It was believed that the experience would transform them into law-abiding citizens by "breaking them down and building them back up." Similar to ISP, boot camps produced dismal results. Of the 24 rigorous evaluations produced, overall findings suggest that boot camps are ineffective in reducing recidivism. One of the main

issues with this type of *treatment* is that they model aggressive behavior. Thus, offenders learn that aggression is an acceptable response, and boot camps may unintentionally toughen them up. Furthermore, any positive changes that result from this form of shock incarceration do not last once offenders return to the community.

Scared Straight Programs

Scared Straight programs are another deterrence-based approach that functioned under the assumption that offenders could be scared away from recidivism. These programs initially involved bringing juveniles into an adult prison setting and allowing them to interact with inmates who shared the hardships of prison life. Today, they are less confrontational and more educational by providing prison tours and orientation sessions.

In a systematic review of Scared Straight evaluations, researchers found very little deterrent effect. In fact, these programs were believed to have possibly caused more harm than good to participants. Among studies that reported failure rates for participants, the program was shown to have increased the percentage of new offenses by anywhere from 1% to 30% when compared to a no-treatment control group. In determining why such increases occurred, researchers believed that the participants viewed the experience as a challenge to prove that they were not scared. As a result, they may have received reinforcement and achieved status from their delinquent peers.

Other Ineffective Treatment Approaches

In addition to deterrence-based programs, researchers have discovered that correctional programs that demonstrate a nondirective therapeutic or *talking* approach are also ineffective. It is suggested that these programs can convince offenders to change through techniques such as lectures and general discussion. Yet, research has consistently found that this form of treatment does not work.

In particular, group counseling and psychotherapy have been implemented with sex offenders with the hope that focusing on past events can

help these offenders gain insight into their behaviors. Furthermore, behavioral treatment for sex offenders has also been used. This approach involves targeting deviant arousal through conditioning and teaching skills related to interactions with age-appropriate individuals. In both cases, these forms of treatment have been found to be ineffective and, at times, harmful.

Additionally, some treatment approaches emphasize the need for interaction between the offender and victim as a means of restoring balance and reintegrating the offender back into the community. This form of treatment, known as *restorative justice*, involves victim-offender conferences. These meetings bring the victim, the offender, the victim's family, community members, and a facilitator together in one place so that the offender can seek forgiveness and restoration. Although these programs may be appealing to victims, evaluations of this program find that, on average, it does not reduce recidivism among adult offenders. This is likely a result of a key theoretical issue: It does not target crime-producing factors. Still, there is some modest support for restorative justice, particularly among juveniles; however, its effects on recidivism are weaker when compared to rehabilitative programs that target criminogenic needs.

Another form of treatment that has been on the rise since the early 2000s has been faith-based programming. These programs vary in their approach to changing criminal behavior and thus have produced a mix of results regarding their effectiveness in reducing recidivism. However, one key factor does stand out in the literature on this topic. When faith-based programs incorporate evidence-based practices, specifically CBT, they do produce better results.

This research reveals that intermediate punishments are unlikely to reduce recidivism. Additionally, programs that use *talking* cures without providing CBT are ineffective. Finally, when programs fail to target high-risk offenders and criminogenic needs, they also fail to significantly change offender behavior.

INMATE CLASSIFICATION, METHODS OF

Inmate classification is a procedure in which incarcerated offenders are placed into varying custody levels based on a professional assessment. Each custody level is designed to match an individual offender's needs with available correctional resources. Classification based on custody level assigns offenders to specific facilities and dictates the level of supervision and treatment they will receive. This entry focuses on types of classification methods, the implementation of classification decisions, and potential barriers to classification.

History of Inmate Classification

Historically, inmates were segregated to prevent harm to themselves and others and to ensure the safety of facility staff. It was thought that full segregation of offenders would increase security and management and decrease the likelihood of recidivism. As the incarcerated population grew over time, segregation was no longer feasible. Inmates were housed together, often multiple offenders to a cell. The need for correctional facilities grew, and prison officials sought to find an effective solution to prison overcrowding. Prior to the 1870s, inmates were classified based on the offense they committed, keeping those who committed violent offenses from those who committed nonviolent offenses. This approach allowed correctional professionals to best determine the appropriate form of punishment for a given crime type. As the field of corrections evolved over time, so did inmate classification methods. Instead of classifying individuals based on offense type, offenders were classified based on their personal characteristics, then founded in clinical or treatment approaches.

Methods of classification are often based in fact: What is known about a given offender. For example, three variables often used to classify offenders are age, length of sentence, and job performance or employment. Age is often utilized in classification decisions as, empirically, younger inmates tend to have higher rates of disciplinary infractions than older inmates. Research has consistently shown a link between age and one's

involvement in criminal activity. In the 1980s, the length of one's sentence was a leading consideration in the classification of offenders. It was believed, the longer one's sentence, the greater the risk posed. One's history of employment and current employment status are also considered. Empirically, inmates who are employed are less likely to incur a disciplinary infraction.

Still, other facilities have tried a quasi-token economy to classify inmates. In this setting, offenders are able to progress through a correctional system by achieving certain tasks. Tasks can range from education programs (i.e., obtaining one's GED) or gaining a vocational certification (i.e., carpentry certificate). Token economies may not be ideal for serious or violent offenders as interactive programming may allow for additional opportunities to commit crime.

Classification comes from the idea that inmates are a heterogeneous subgroup. It is, thus, realistic to categorize them into meaningful subdivisions. Although criteria for classification varies by agency, inmate classification is one of the most significant postsentencing decisions made, as it involves the consideration of safety, economics, and quality of life. It allows facilities to aggregate individuals into subgroups that share common attributes, characteristics, symptoms, or behaviors.

Initial classification occurs upon facility admission. When an inmate arrives at a correctional facility for intake and processing, the inmate is assessed as to the risk he or she poses to himself or herself, the other inmates, and facility staff. The risk to recidivate and one's escape risk are also considered. Based on a battery of assessment tools, inmates are classified into a category, security level, or transferred to a different facility better able to suit their needs. Each assessment tool is conducted by a trained professional who works for the correctional facility. This individual uses standardized measures (discussed later in this entry) to make an informed decision as to the classification of each individual offender.

Subjective and Objective Classification

James Austin provides two categories of inmate classification: subjective and objective. Subjective classification is based on the experience and

judgment of an administrative professional. As the use of inmate classification grew in the 1980s, states utilized a subjective classification approach. Subjective classification involves the use of broadly defined criteria, analyzing inmate characteristics and the physical design of the facility. Because correctional officials made classification decisions across large populations, consistent classification was difficult and led to high rates of error. The use of subjective classification methods in large correctional facilities proved to be especially difficult as situational factors and staffing issues significantly contributed to variations in risk. Subjective classification can be overridden, however, occurring 5–15% of the time, as often, recommendations from one correctional professional vary to another.

Objective classification is a more formalized approach to categorizing offenders, and most correctional agencies have moved toward adopting this method. Originally intended for those under community supervision, objective classification stresses equity in decision-making and is conducted using a standardized form to assess the risk and need of the individual offender. Objective assessments provide recommendations for custody decisions and programming and are empirically shown to better facilitate treatment assignments. Austin recommends objective classification to include three principles. First, objective classification should be based upon a reliable and valid criterion. The utility of this criterion should be founded in empirical evidence and extensive research. Second, each classification evaluation should be conducted by a professional who has completed a specialized training program. Because this individual makes classification recommendations, he or she should maintain competency with annual refresher training. Finally, each classification decision should be documented and periodically reevaluated. Consistency can be achieved through the use of interrater reliability assessments. Having an individual or team of individuals serve as interraters whose purpose is to randomly select and review previous assessments will increase the reliability of the classification method. Furthermore, such a process allows for continuity and consistency across departments.

Classification Methods

Most correctional agencies have classification processes for inmates, and all 50 U.S. states have at least one form of a classification approach. Classification allows for treatment and programming recommendations, but it also allows facilities to house inmates based on security or safety risk. Sorting inmates by level of risk can benefit the entire facility, both operations and personnel. Classification methods are, ideally, constructed in a way that allows for the assessment of changes in dynamic factors: attitudes, behaviors, or status. Former classification methods were based on categories (e.g., military status, marital status, level of education) that proved to have very little use in predicting prison misconduct. Over time, these ideas were abandoned. Now, successful classification tools are extensive, allowing for the classification of offenders across attitudes, offense type, race, and gender.

Successful tools are written objectively, providing clear operational definitions to avoid ambiguity. Widely accepted assessment tools (leading to classification) have been tested to ensure reliability and generalizability across offense type. Such tools include both static and dynamic factors. Consider, for example, the Level of Service Inventory-Revised (LSI-R). The LSI-R is an actuarial risk assessment tool used for the classification of offenders in over 200 countries worldwide. The LSI-R is not offense-specific; thus, it can be used to assess risk for offenders who commit multiple crimes across offense types. The tool assesses risk via a structured interview between a trained correctional professional and the inmate. Based on the inmate's responses, the correctional professional calculates a risk assessment score. The score is based on a 54-item survey answered by the professional corresponding to the interview responses of the offender. Both static (e.g., criminal history, number of times arrested) and dynamic factors (e.g., substance abuse, unemployment) are considered. The score, ranging from 0 to 54, places the offender in either minimum, medium, or maximum risk-level categories. This level of risk translates to the type of housing, treatment, (un)restricted access, earnable good time credit, and programming the offender will receive while incarcerated. Periodically, throughout the inmate's incarceration, the inmate will be reassessed via the LSI-R. Based

on subsequent reassessments, the classification level may increase, decrease, or stay the same.

Risk assessment tools, like the LSI-R, aiding in the classification of offenders are useful as they have the ability to assess multiple factors related to recidivism. Because no one risk factor is sufficiently related to recidivism that it can explain reoffending entirely on its own, these assessments allow for professionals to classify inmates to best ensure safety, the meeting of treatment needs, and appropriate referrals for programming and educational courses. Some risk assessment tools are offense-specific in that they were developed strictly for offenders who committed a particular crime (e.g., Static-99 for male sex offenders).

Risk assessment tools and classification methods are utilized in release decisions (i.e., probation and parole). Such data allow the parole board to make informed decisions based on the risk posed to the community as relative to the nature of the time one spent incarcerated. Classification while incarcerated can carry over into the community, further dictating the level of treatment, surveillance, and programming to be received. Although risk assessment tools that contribute to classification methodology have been validated on a wide range of populations, it is important to note that classification categories vary from state to state and at the federal level. States may adopt levels or categories to suit their specific offender population.

U.S. Federal Classification

While classification varies from state to state in the United States, it also varies from the state agencies to the U.S. federal system. The federal prison system (122 facilities) classifies offenders by security levels: minimum, low, medium, high, and administrative. *Minimum* federal facilities are dormitory-style buildings, allow access to work and program privileges, and have limited or no perimeter fences. These facilities are referred to as *federal prison camps*. *Low* federal facilities are dormitory style with doubled fences and a higher ratio of staff to inmates. *Medium* facilities have an even greater ratio of staff to inmates and are protected by doubled fences, internal control systems, and electronic detection. *High* security facilities, known as *U.S. penitentiaries*, have perimeter walls or reinforced fences, the highest ratio of staff to

inmates, and exercise control over all inmate movement. Finally, *administrative* facilities serve a special purpose. These facilities house pretrial detainees, inmates with serious medical conditions, or inmates who pose an escape or violent risk. All but one federal administrative facility is capable of holding inmates of all security levels.

Overclassification

Classification of offenders is an important process to ensure the safety of offenders and staff and the routine operations of a correctional facility. However, given the large number of inmates in the United States, classification is difficult. Furthermore, continued classification efforts and reclassification create the potential for errors. Errors in classification tend to be false positives or overclassification. Overclassification is not only inefficient but also costly. It further contributes to overcrowding and increases in inmate-related issues, violence, and disturbances. Objective classification based on actuarial risk assessment tools can decrease these false positives.

INMATE CODE

The inmate code is part of the prisonization process whereby new inmates assimilate to life behind bars. The inmate code refers to an informal set of

rules or norms that govern the behavior of incarcerated people. While there is some variability in the content of this code across time and context, there is widespread agreement that the norms of behavior embodied in the inmate code are distinct from the norms of mainstream society and contrary to the formal behavioral rules of penal institutions.

As a consequence, the inmate code provides normative support for rule and law violations among inmates and contributes to a social milieu in prisons that encourages disruptive and illegal behavior. Normative support makes it psychologically easier for people to commit acts that are regarded as criminal or deviant by mainstream society because the perpetrators themselves actually regard their behaviors as correct and appropriate. By relieving perpetrators of feelings of guilt, shame, or remorse, which usually accompany norm or rule violations and might otherwise inhibit criminal behavior, the inmate code makes it easier to commit criminal acts.

This entry begins by reviewing the origins of the inmate code. Next, code content and adherence to the inmate code are discussed. The entry concludes with a brief discussion of ongoing research needs.

Origins of the Inmate Code

There are at least two schools of thought on how and why the inmate code has evolved. Some criminologists such as Gresham Sykes argue that the inmate code is a reaction to the social realities of prison life. In other words, the *pains of imprisonment* or the deprivations associated with confinement create a unique social climate that has given rise to distinct norms and values. The inmate code is simply a functional response to the realities of prison life. It is a product of the prison environment and reflects the values and corresponding norms of the prison subculture.

Other criminologists, including John Irwin, a former inmate himself, argue that the inmate code is the result of the importation of underclass values and experiences into the prison environment due to the nearly exclusive use of imprisonment against members of the lower class. In other words, the life experiences and social mores of the inmates who are sent to prison inform the content

of the inmate code. In essence, the inmate code is *imported* into prisons with the prisoners. Prisoners need not adapt by accepting *new* norms or rules that comprise the inmate code, rather the inmate code is consistent with the product of the normative proscriptions of lower-class culture in general. Inmates just continue to act in conformity with their pre-prison values and norms after incarceration. According to this view, while the inmate code may be counter to the norms and values of mainstream society, it is not the product of the prison environment.

While these theories are sometimes presented as inconsistent alternatives, research suggests that both of these theories have value in understanding the origins of the inmate code and that these theories can be integrated to some extent. In other words, contemporary research reflects that both the prison environment and the pre-prison experiences of prisoners impact the inmate code. For example, individual-level characteristics may affect the degree to which the inmate code is internalized by a particular inmate just as organizational or systemic variables associated with particular prisons can influence inmate culture at those prisons. These synthetic approaches increase both explanatory power and comprehension of how the inmate code is formed and maintained.

Code Content and Demographic Status

As is often the case with criminological research, almost all of the older work and much of the contemporary work concerning the inmate code focus on male subjects. As a consequence, what is presented as generic discussions of the inmate code are often, in reality, reflective of what is normative for male prisoners. Early work with male inmates suggests that there was a high degree of group solidarity and cohesion among inmates coupled with a high degree of antagonism toward all staff. Toughness, minding one's own business, loyalty to fellow prisoners, and avoiding any cooperation with administrators or staff were all frequently mentioned as characteristic of the inmate code. This *us versus them* mentality is apparent in early formulations of the code, which noted widespread acceptance of various rules including prohibitions against snitching on fellow inmates and exploiting or cheating fellow prisoners. Early formulations

of the code also emphasized the importance of noncooperation and defiance toward guards and other prison staff.

Some recent research suggests that the *esprit de corps* among inmates, if it ever really existed, has given way to a far more brutal "dog eat dog" approach to inmate relationships. This *new code* among male inmates emphasizes a pathological fixation on hypermasculinity that prizes aggression and concealment of vulnerability and emotion. Inmate solidarity appears to have fragmented to some extent, giving way to racial and ethnic cohesion, with the result that prohibitions against snitching, exploitation, and deceit may only apply to inmates belonging to the same racial/ethnic group. There is even evidence that the new code condones sexual exploitation of weak inmates and/or inmates of different ethnicities. One theory as to why the inmate code may no longer discourage mistreatment of all fellow inmates is that the influx of hard drugs like crack and heroin into the prisons has fractured and disorganized inmates. These changes may also reflect contemporary changes to urban underclass culture in general, which has been found to overemphasize respect and toughness and condone brutality and abuse.

The rise and proliferation of gangs among male prisoners has also changed the inmate code. In many places, gang loyalty has supplanted notions of inmate loyalty. Gang involvement in drug trafficking has also shifted priorities. Whereas earlier generations of inmates valued solidarity and adherence to the code as a vehicle for defying the goals of prison administrators and attaining respect, there is some evidence that gang-involved prisoners today are often interested in keeping the peace and at least nominally cooperating with staff in order to protect their illegal money-making activities from interference. Although it is important to note that while gang leaders may discourage violence and rule breaking that contribute to chaos and invite crackdowns, violence remains an integral part of establishing and maintaining control over drug trafficking within prisons.

While work involving female inmates is more limited, some significant insights about the social world of imprisoned women have been gained from past research. Early research suggests that female inmates organize their social life around

small group attachments (*pseudo-families*) and that as a consequence, prisoner solidarity was of less importance and informing and snitching were more acceptable. Building on this prior work, Barbra Owen noted that the social world of female prisoners was intensely relational. Emotionally intimate but nonsexual *play families* and intimate dyads characterized by intense emotional relationships were common. Owen's work suggests that the cultural life of female inmates revolves around the focal concerns of privacy and maintaining relationships with those on the outside, especially children.

These focal concerns provide the normative basis for a number of informal *rules* that guide female inmates' behavior. The privacy-based rules include the following: do not gossip or betray confidences, stay out of other inmates' affairs, and do not touch other inmates' things or invade their space without permission. The rules related to the importance of outside relationships included shunning or sanctioning those convicted of hurting a child or parents and a taboo against commenting on the length of someone's sentence. Other rules, which appear to be related to overcrowding, include rules about cleanliness and hygiene.

Age has a somewhat ambiguous relationship with the inmate code. On one hand, there is some evidence that young (20s) and old (40 plus) inmates may be less committed to the inmate code. On the other hand, there is evidence that old heads, people who have done a long stint in prison, are more committed to various aspects of the code than young and impulsive short-timers.

The inmate code and the wider process of prisonization appear to occur cross-culturally. In other words, there is evidence of a nonconformist prison culture across the globe, albeit with some significant local differences. For example, the degree to which the code reflects inmate solidarity can vary by country.

Adherence to and Enforcement of the Inmate Code

Adhering to the inmate code is, at least in some contexts, a means of acquiring respect for both male and female inmates. Similarly, departures from the code earn inmates the contempt of their fellow prisoners. Inmates often place a heightened

value on respect and vociferously identify with the code and see adherence to it as essential to their self-identity and respect.

Despite widespread endorsement of the code and espoused respect for those who adhere to it, in practice, adherence to the inmate code is neither universal nor constant. Just as in other societies, individuals sometimes decide to violate the norms or rules in pursuit of self-interest. For example, it is not unusual for incarcerated men and women to turn informant and testify against other prisoners, even their friends or associates, in exchange for sentence concessions or other benefits.

Part of the reason for variability in adherence is uneven acceptance of the code by the inmate population. Charles Terry's work, for example, suggests that only some male inmates—he denominates them as *convicts*—embrace the code and live by its dictates; the rest do not accept the code and do not try to emulate it. Adhering to the code may be adaptive because earning a reputation as a *good convict* appears to insulate inmates from victimization to some extent. Other researchers suggest that adherence to an aggressive, exploitive, hypermasculine code is context-specific and may evolve and change over time. Research on female inmates revealed similar variability in the degree to which inmates subscribe to the inmate code. Such variability is to be expected, as perfect normative compliance and a complete absence of deviance exists in no known society.

Enforcement of the inmate code also varies across time, space, and context but it is, at times, ruthlessly enforced. Male inmates, in particular, are known to informally sanction code violators with beatings or even death. Many male inmates regard violently defending their honor in the face of disrespect as essential to the code and maintaining respect among fellow inmates. Failure to do so entails a loss of respect that may result in victimization. Women too have been known to violently sanction code violators, although such violent enforcement appears to be less common among women than men. Lesser sanctions such as verbal reprimands, loss of social esteem, social exclusion, and other consequences not involving violence are also sometimes imposed on inmates who violate the code.

Enforcement of the code in some prisons appears to rest with inmate leaders. Other research

suggests that all inmates have a duty to enforce the code. Inmates who identify with the code often offer justifications for their occasional departures from it, which mirror the types of accounts used by those on the outside to justify their criminal or deviant behavior, suggesting that the code is reflective of sincerely held subcultural norms.

Future Research

Given the importance of the inmate code in shaping interactions among inmates and its potential to contribute to violence and interfere with rehabilitation, it remains an important area for study. Ongoing research in a variety of contexts with diverse inmate populations is necessary to keep abreast of how the content of the code varies among different groups of inmates and under different circumstances. For example, there is some evidence that direct supervision and other progressive penological approaches can blunt enthusiasm for and adherence to the inmate code. Further developing understanding is necessary if authorities wish to reduce the influence of the code and control its negative affect on inmate behavior.

INMATE DENIAL OF CRIMINAL RISK

Denial and minimization refer to some degree of refuting facts related to an offense whereby denial may be complete refutation and minimization may include some degree of refusal to acknowledge victim impact, the commission of an offense, wrongdoing or seriousness of the offense, and/or the need to be sanctioned or receive treatment as a result of the offense behavior. Depending on the offender's criminal behavior, an offender's denial may refer to aspects of his or her behavior (e.g., for a sex offender, denial of sexual deviancy; for a batterer, claim of self-defense; and for a murderer, denial of being a violent person). Denial is often deemed a concern by forensic professionals who evaluate and/or treat convicted offenders. In the criminal justice system, it is frequently observed that weight is placed on denial when making decisions regarding parole, judicial sentencing, treatment amenability, and risk of future reoffending. This entry provides an overview of inmate denial of criminal risk by defining denial, examining both its functional purpose and its problematic nature, and finally approaching denial as a responsiveness factor.

Defining Offender Denial and Minimization

Minimization or some degree of denial is expected among offenders, and therefore, there has been plenty of research examining its role and function in correctional settings—both in the community and in institutions. However, the study of denial is plagued by conceptual and definitional problems. Some view denial as dichotomous—either denial is present or absent, and minimization is something different altogether. Some also view denial and minimization as degrees of accepting responsibility, ranging from complete acceptance of responsibility to categorical denial. Still others purport that denial is multifaceted and comprises of several components (e.g., denial of offending, denial of harm to the victims, denial of posing a risk to others, and denial that one needs help or treatment). As such, there is a plethora of ways to measure denial ranging from scales on existing personality measures, such as the validity scales on the Minnesota Multiphasic Personality Inventory or Personality Assessment Inventory, to self-report measures specifically designed to assess denial for a certain group of offenders, such as the Facets of Sex Offender Denial, Comprehensive Inventory of Denial–Sex Offender Version, or Distress and Responsibility Scale for non–sex offenders. Virtually all of the measures of denial use self-report questionnaires, which assess denial as an inferred attitude rather than focusing on it as overt communication and behavior. Although denial is associated with cognitive distortions, they are distinct constructs. To illustrate, many offenders are savvy in using language to minimize responsibility for their offending and may present as socially desirable in a self-report measure. Moreover, it is expected that denial will change, depending on the context (e.g., interviewed in a police investigation, presentence evaluation, treatment assessment, or parole hearing) and on the engagement of the offender in treatment. Hence, the need to employ a suitable and valid measure for assessing offender denial has important implications for treatment and research.

Functional Purpose of Denial

Inmate denial is not surprising to those who work with this population, but it is often assumed that denial is a dysfunctional thing and must be

changed to a more acceptable presentation (i.e., acceptance of responsibility and insight into one's risk). Yet an examination of the noncorrectional research shows that it is widely accepted that denial serves a functional purpose and therefore works as a defense mechanism that reduces anxiety. This purpose is easily recognized among nonoffenders as reducing feelings of anxiety (e.g., denial of the seriousness of one's sickness to make oneself feel secure and hopeful about the future). Yet, denial among offenders is often deemed dysfunctional and in need of being changed. It is important to consider that denial is functional for human beings and that people can benefit from denial. An examination of the literature on excuse-making illustrates that there is a large body of evidence supporting the assertion that excuse-making is normal. There is a plethora of anecdotal experience that people often seek to excuse their behaviors by seeking out ways to avoid internalizing personal responsibility. Empirical research suggests that excusing past transgressions enhances one's sense of self-control over future situations of a similar nature and reduces the dissonance between incompatible cognitions, which causes unpleasant feelings. Furthermore, making excuses can be highly adaptive and frequently healthy. Some research suggests that excuse-making can lead to better physical health, better performance at work, and maintenance of one's self-esteem. In addition to the positive effects of denial on the individual, there are also positive effects associated with how the denying individual is perceived by observers. For example, when excuses are made for not fulfilling a social obligation, there is a tendency for social impressions to be more favorable, especially when using an excuse that attributed responsibility to an external source, which was uncontrollable and unintentional. On the other hand, when one does not give an excuse, the individual is perceived unfavorably.

It is important to note that denying or minimizing offending behavior is not inconsistent with an understanding of people in general. The normative function of an offender's excuse-making is to reduce anxiety—the more one denies, then the individual experiences less anxiety and is able to maintain a positive impression of oneself. A particular useful function of denial for an offender is how it influences the perception of others.

Empirical research that has examined the function of denial by offenders has shown that denial serves a favorable purpose for offenders. For example, parole boards tend to assess denying offenders as less likely to commit further offenses than those offenders who took responsibility for their criminal behavior, and treatment providers assessed admitting sexual offenders at a greater risk to reoffend than those who denied or minimized their risk. Hence, there is clearly the potential for the expression of denial to benefit the offender.

Therefore, it is important to recognize that denial is not only functional for people in general but very beneficial for an offender to deny or minimize his or her offending behavior and risk to reoffend. Offenders, like most individuals—offender or not—may regard denial as a security blanket that protects and serves them. As a result, it is likely to be a challenge to encourage offenders to relinquish their denial.

Exploring the Problem With Inmate Denial

As denial serves the offender well, it might not be clear why inmate denial is a problem. The notion that denial is problematic has often been translated into an illusory correlation with recidivism risk. This has been examined in the sex offender literature. Meta-analytic studies have not supported a significant association between denial and sexual recidivism, and denial was identified as a noncriminogenic factor. Subsequent research has shown that denial may predict sexual recidivism only for some groups of sexual offenders (e.g., low-risk offenders in general, high-risk offenders after treatment), but the pattern of results has been inconsistent across these studies. Most of the available evidence seems to suggest that denial is not an important predictor of sexual recidivism or other types of recidivism risk.

On the other hand, a practical issue arises in the treatment of offenders who deny. Many offenders, particularly sex offenders, go untreated because either treatment providers interpret denial as an indication that the offender is unamenable to treatment or the requirement for the successful completion of a treatment program includes acceptance of responsibility. However, terminating an offender from a program due to the exhibition

of denial is problematic. For example, it may be difficult for supervising staff (e.g., probation) to sanction consequences for noncompletion of treatment when the treatment staff terminated the offender from the program. Also, the ethical dilemma of releasing an offender to the community without engaging him or her in any form of intervention is troublesome. The empirical evidence shows that greater denial and minimization are associated with lower motivation and more negative perceptions of treatment. Specifically, measures of offender denial are significantly correlated with scales of treatment motivation, and sex offender denial has been shown to be associated with lower levels of treatment engagement.

Hence, although offender denial may not directly be associated with increased risk of recidivism, it certainly poses a problem in terms of rehabilitation.

Inmate Denial as a Responsivity Factor

Rather than construing denial as a risk factor, denial may be more productively approached as a responsivity factor that presents as an obstacle for an offender to engage in treatment. According to the Risk-Need-Responsivity principles, treatment and supervision are most effective when geared toward higher risk offenders (Risk principle), when known criminogenic needs (crime-producing factors) are targeted for intervention (Need principle), and when individual variables that impact a person's ability to respond most effectively to interventions are taken into account by matching offenders to interventions and practitioners (Responsivity principle). Little attention has examined noncriminogenic needs that could be construed as responsivity factors. It has been suggested that denial/minimization, personality disorders, hostility, substance abuse, and mental health history should be included in the list of responsivity factors. Such factors may not be directly associated with recidivism risk, but they may impact the feasibility of an offender to participate in treatment. According to the responsivity principle of the Risk-Need-Responsivity model, denial may not be a risk factor, but its presence has strong associations with lower levels of treatment engagement and decreased motivation for treatment. Hence, when offender denial is present, treatment

should be tailored to the individual offender in order for the treatment to be most effective.

It is important to recognize that denial may be functional for an offender, and therefore, transforming denial in treatment can be difficult. In light of the associations found between denial and treatment motivation, a different type of engagement may help to increase the benefits of treatment. Treatment providers could facilitate change (e.g., replace or transform denial) among denying offenders to a more prosocial and functional anxiety-reducing behavior, which promotes both accepting some degree of responsibility and reducing overall feelings of anxiety. An appropriate assessment of denial and minimization and an understanding of the function that denial serves for an offender are necessary to identify the type of denial present (e.g., Is it challenging to see himself as a sex offender? If she says she abused her child, is she worse than her own abusive father?). Identifying the type of denial allows one to examine what type of denial is inhibiting an offender from engaging in treatment. By understanding the type of denial, therapy can focus on understanding what risk is and what kinds of things the offender sees as preventing him or her from offending again, while motivating him or her to find known effective ways that have prevented others from further criminal offending.

INMATE RESEARCH INTERVIEWS

Inmates, often called *offenders* (particularly by corrections professionals), are incarcerated individuals currently serving time in a jail, a federal or state prison, or another type of correctional location such as a community reentry center or court-mandated rehabilitation facility. Inmates do not include individuals on probation or parole. Researchers seeking to interview inmates face a unique set of challenges. These challenges include gaining access to the target population, navigating the processes of ethics committees and institutional review boards (IRBs), constructing interview instruments including consent and disclosure forms, self-presentation and self-disclosure both in the correctional facility and in the interview setting, negotiating time and data-gathering restraints unique to prison research, and presenting honest, accurate analyses of inmate interview data.

Interviewing is a qualitative data-gathering technique that typically involves one-on-one (although interviews can also be completed in groups), face-to-face conversations between the interviewer and the interviewee. The length of time an interview takes depends on the nature of the research questions being investigated, the skill of the interviewer, the willingness of the interviewee, and other potential restraints posed by the setting itself.

This entry focuses on addressing these issues and explaining standard techniques for their successful navigation.

Gaining Access

In the United States, prisons are managed either by the federal government, by state departments of correction (DOCs), or by private companies. Local, municipal, or city governments typically oversee jails. Gaining access to an incarcerated population for the purposes of conducting research can be difficult and time-consuming. The first step often means going through the agency that manages the prison or jail. Because there are often multiple levels of permission required before a researcher is granted access, the most expeditious route to beginning the process is to contact a human services professional at the jail or prison one wishes to access. Most prisons have individual web pages listed on the DOC or Federal Bureau of Prisons websites. Here, the contact information for a prison representative can usually be found. This person will likely refer the interested party to a research and development professional at a higher level of management who will then be able to guide the investigator through the necessary steps.

Every organization has a different set of requirements for conducting research. However, most DOCs and the Federal Bureau of Prisons use a standard format of internal, institutional review for proposed research projects. This means that individuals wishing to gain access for a prison study must submit their proposal to the institution's Research and Development Board (this may also be called an *ethics committee* or an *IRB*). Typically, the contact person for the Research and Development Board will provide documentation pertaining to the institution's particular submission requirements.

The requirements for research proposals submitted to a correctional institution's review board are often very similar to those of a university's IRB. The difference between typical human subjects research and research with incarcerated individuals, however, is that inmates are considered a *high-risk* population, making the process of gaining access more difficult.

IRBs and Incarcerated Populations

High-risk populations refer to a group of people who may be unable to understand the potential risks of participating in research or who may be

easily manipulated by a researcher. Other high-risk populations include children, the elderly, and people with certain types of medical illnesses or certain social or developmental disabilities. There are a number of reasons why inmates are considered at high risk. First, because prison inmates are involuntarily incarcerated, their risk of feeling coerced to participate is heightened. Inmates may believe that their participation in research is a requirement of their release from prison and, thus, may not feel that they may decline to participate. Second, prison populations include a disproportionate number of racial minorities, people of low socioeconomic status, and individuals with little or no formal education. As a result, their ability to give their full, informed consent to participate may be significantly decreased.

There are several ways to combat these issues in order to ensure inmates' safety and rights. IRBs at both the correctional institution and the university will expect researchers to account for the issues of high-risk populations in their consent and disclosure forms and interview questions.

Consent and Disclosure

For all human subjects research, gaining an individual's informed consent to participate is (on some level) almost always required. This practice reduces the risk of deception and coercion that a researcher may intentionally or unintentionally create. For research with inmates, several considerations must be made when constructing consent forms.

First, forms should be written at a sixth-grade reading level. Writing consent forms at this reading level ensures that an undereducated individual might better comprehend the rights afforded to him or her. Consent forms should state that an inmate's participation is not required and will not impact the inmate's treatment within the prison, the conditions of the inmate's parole, or the inmate's release requirements. In addition, consent forms should state that most information will be kept confidential and that pseudonyms will be assigned; if an interviewee states that he or she is being harmed, if the inmate plans to harm himself or herself, or if the inmate plans to harm someone else, then the proper authorities must be notified.

Finally, consent forms should include the contact information of the principal investigator and additional questions the interviewee has regarding consent. However, it may be acceptable to include only the contact information of the university's IRB if the researcher does not feel comfortable disclosing her or his personal information.

Interview Instruments

Constructing interview questions designed for incarcerated individuals can be challenging for several reasons. Primarily, questions asked of an inmate should be worded in ways that do not require the inmate to disclose information that could inadvertently cause him or her to admit to committing a crime. This is particularly problematic because while an inmate is in prison because he or she was *convicted* of a crime, it cannot be assumed that the inmate *actually committed* a crime. In fact, in many cases, an inmate's future appeals or parole hearings may hinge on the inmate's continued insistence that he or she is innocent.

Researchers should take these concerns into account when constructing interview questions. For instance, rather than asking, "Why did you commit the crime that sent you to prison?" the question may be worded as follows: "Why would someone similar to you commit the crime for which you are currently incarcerated?" While this alternative wording may seem cumbersome, it is essential that researchers prioritize the continued protection of their subjects not only to protect the rights of the inmates but also to protect themselves. In rare cases, a researcher (and the gathered data) may be subpoenaed and required to give testimony in court regarding the content of an interview. If questions are worded innocuously from the beginning, a researcher's risk of having to disclose sensitive and potentially damaging information about the participant is greatly reduced.

Interview Setting

Conducting interviews in a prison requires an investigator to consider certain elements often not present in traditional interview settings. For instance, as a visitor inside a prison, the investigator

will likely be required to wear certain types of clothing (e.g., long pants, closed-toe shoes, no jewelry, avoiding certain colors). The prison usually provides the investigator with a list of acceptable and unacceptable clothing, but if it does not, then the researcher should ask for such a list.

Certain colors may be associated with gang affiliation, and types of clothing may be considered inappropriate in a prison setting. These issues will often go beyond what a researcher might consider appropriate himself or herself. For instance, the colors red and blue represent well-known national gangs. However, other colors might be associated with more local or regional gang membership, with which the investigator may not be familiar. The prison will generally explain what types of clothing are acceptable, and researchers should be sure to follow these guidelines in order to avoid potential setbacks.

Depending on the requirements set forth by the DOC review board and the university's IRB, other restrictions may be present in the prison setting. For instance, it is possible that an investigator may not be permitted to record interviews conducted with inmates due to issues of confidentiality. If this is the case, the researcher must be prepared to take notes by hand and may have to sacrifice transcribing many direct quotes. Interviews that are not recorded often take longer than anticipated, which means the researcher should be careful to watch his or her allotted time frame.

Prison is a highly structured environment, and inmates are required to be in specific places at predetermined times. If an interview takes longer than anticipated, the researcher may be forced to finish before he or she has collected all the desired data.

In addition, in prison, a researcher can never be assured that the interview is being conducted in complete privacy. For the researcher's safety, staff may be required to remain nearby in case of an emergency. Similarly, the investigator may not be allowed to hand items (such as pens or paper) directly to the inmate. In these cases, researchers will be instructed to slide items across a table, rather than reach across it to give something to an inmate.

Many of these issues are things that novice researchers may not anticipate upon their first

entry into prison. They also differ for every type of prison institution, and so researchers should ask as many questions before their first trip as possible to avoid delays.

Finally, and particularly for first-time prison researchers, the experience of spending several hours a day for perhaps many months inside a prison can become emotionally taxing. The strict physical requirements, the depth and sensitivity of the information gathered during interviews, as well as the processes of entry and exit (e.g., searches, metal detectors, identification requirements) could affect a researcher personally. These issues should be taken into consideration before attempting to interview inmates.

Inmate Representation and Data Presentation

Finally, and perhaps most importantly, prison researchers have a unique ethical duty to represent inmates in prison responsibly through the publication and presentation of their data. As with all human subjects research, investigators must report the findings of their research as accurately and respectfully as possible. With inmate subjects, however, it is important to remember that the *truthfulness* of the answers given in an interview is couched in a context that may be highly politicized and one in which the inmates' rights are inherently diminished. The experience of being in prison is a difficult one, and for many inmates, simply the chance to tell their side of a story or discuss their motivations may be the most important benefit of their participation. The honesty or dishonesty in the answers they give is something of which a researcher can never be fully certain. For that reason, prison interview data must be taken for what they are: an answer to a question or a story told that was true in the moment. Presenting one's data as such and fully expounding upon the context in which the interviews were conducted serve to create a more honest representation of others' stories.

Lastly, a researcher's own biases may become more acute due to the prison setting and the information the researcher received. Acknowledging the characteristics of oneself that may have influenced the data (e.g., gender, race, class, education, personal experiences) can have an important impact on the honesty with which research results

are presented and read by their respective audiences.

Interviewing inmates is often a difficult and daunting task that, just like any type of research with high-risk subjects, requires practice and sensitivity to issues that go beyond one's initial expectations. However, the data and information received from this diverse population can lead to some incredibly rich and important research results.

INSTITUTIONAL VIOLENCE AND MISCONDUCT

Violence and misconduct in correctional institutions are of great concern to inmates and prison staff. Inmate classification and programming, facility architecture, and staff procedures are all oriented toward minimizing the occurrence of these behaviors. Interest in institutional violence and misconduct, however, is not limited to those who live and work in this setting. Criminal justice researchers study these behaviors to inform the basic science and contribute to more effective

prison administration and enlightened public policy. Legislatures and the courts may draw upon these research findings in protecting inmates from cruel and unusual punishment. For example, in 2003, Congress passed the Prison Rape Elimination Act. Forensic mental health experts and juries are consumers of research regarding prison violence and misconduct as well. To illustrate, a routine consideration in death penalty sentencing is whether the capital offender is likely to engage in serious violence in prison if sentenced to life without parole. This entry provides an overview of violence and misconduct in correctional institutions, including relevant data, rules, and sanctions.

Data Sources

Most corrections departments have internal research branches that collect and analyze data regarding inmate misconduct and particularly inmate assaults. These data provide a metric both for evaluating effectiveness of procedures and for reporting to legislative and executive oversight. Institutional databases, as well as individual inmate files, are also mined by external researchers. Researchers may also utilize inmate surveys if certain types of violence are thought to be underreported in official disciplinary records. Unreported prison violence is most likely to involve minor assaults and sexual intimidation. Official data are likely to capture virtually all assaults with serious injury, homicides, and staff assaults.

Rules and Sanctions

Prisons are highly structured environments with extensive rules governing inmate behavior. These rules range from uniform standards and cell hygiene, to property restrictions; they cover a range of behaviors: inmate movement, disobedience of a staff directive, substance abuse, and assaultive misconduct. Corrections staff are given much authority and latitude in determining whether an infraction has occurred. Typically, infractions are grouped in three to four levels of seriousness. Sanctions escalate with the severity of the infraction, as well as the frequency of infractions committed by an inmate. These sanctions primarily involve loss of privileges, cell restriction (i.e., *the hole*), and/or transfer to a higher security

classification/custody. Occasionally, prison misconduct may result in a criminal prosecution.

Research Findings

In the face of so many rules and stringent enforcement, it is not unusual for inmates to receive a *ticket* or *shot* for an infraction. In some jurisdictions, more than 40% of prison inmates will be cited for a disciplinary infraction of some sort each year. Most of these, however, are for minor violations. This leads to the first important observation regarding prison misconduct and violence: The more serious the misconduct, the less often its occurrence. This same observation applies to prison violence. To illustrate, while 2–3% of inmates may be involved in at least a mutual fistfight in any given year, only one in 200 annually perpetrate an assault resulting in injury and only one in 500 an assault with serious injury.

These data illustrate a second primary finding regarding prison violence in the modern era: Serious violence in prison is quite infrequent. This finding may be surprising, as popular media often depict prisons as rife with stabbing (i.e., *shankings*) and killings. In fact, the annual frequency of inmate-on-inmate homicides in state prisons throughout the United States has declined more than 90% in the last 40 years, and now the number is fewer than four per 100,000 inmates. In many jurisdictions, prison homicides are even less frequent. With over 150,000 inmates in custody in Texas prisons, there was only one inmate homicide in 2014 and only two in 2015. Despite more than 45% of state prison inmates serving sentences for violent felonies, homicides in prisons nationwide average less than one-ninth the rate of homicides in the open community among a demographically matched sample. Homicides of prison staff by an inmate are extraordinarily rare, with annual rates of fewer than 1 per million inmates annually and some jurisdictions never having had a staff member murdered in the line of duty.

Theoretical Explanations for Prison Misconduct

Theoretical explanations for prison misconduct involve four perspectives: deprivation, importation, management, and general crime/deviance.

Deprivation theory focuses on the adaptations to the environmental pains of prison, including restrictions, reduced autonomy, isolation from social supports, access to goods, and gang activity. *Importation* theory examines prison misconduct from the perspective of the attitudes, experiences, and features the inmate brought into prison, such as criminal history, conviction offense, demographic characteristics, and mental health and substance abuse histories. *Management* processes include classification and custody level, crowding, staff morale and training, and administrative effectiveness. *General theories* of crime and deviance are utilized by some scholars to explain prison misconduct as well. For example, strain theory posits that people naturally abide by rules, but they may experience pressure or *strain* to offend. Such concepts may bridge deprivation, importation, and management factors.

Both deprivation and management are associated with the context of prison. Broadly, researchers have found that the latter contextual factors exert a greater influence on the occurrence of prison misconduct and violence than inmate-specific features. Illustrative of this finding, rates of serious violence within the Federal Bureau of Prisons vary widely from one U.S. penitentiary to another in any given year, even though these reflect the same level of security, identical procedures and regulations, and highly similar programming.

Among institutional factors, higher levels of misconduct are more consistently found in prisons that have higher concentration of inmates who are under age 25, Black, or convicted of violent offenses. Prisons that are larger and reflect a higher security level have higher levels of misconduct as well. Inmates involved in religious-based programs tend to commit fewer infractions.

Among the *importation* or inmate-specific factors correlated with prison misconduct and violence, the most powerful is age. Regarding misconduct broadly defined, inmates who are older are less often involved in prison misconduct. Inmates with histories of low self-control are more likely to be involved in prison misconduct, as are inmates associated with gangs. Inmates who have been treated for mental health problems, come from high-deprivation neighborhoods, or have suffered abuse also tend to have higher rates of prison misconduct. A history of prison

misconduct is associated with higher levels of subsequent misconduct.

Regarding prison violence, age at admission to prison and across a prison term is strongly and inversely related to prison violence. This well-established finding has been observed among prison inmates in general, inmates in high security, convicted murderers, and convicted capital murderers. Other inmate-specific factors associated with prison violence include property offense, prison gang membership, sentence length (inversely), and prior prison term. Higher levels of education are also associated with lower rates of misconduct and violence in a number of studies. To illustrate, inmates having a high school diploma or General Educational Development (GED) had about half the prevalence of assaultive misconduct holding other factors constant. Inmates who have stable work histories in the community as well as those who have higher levels of social support (e.g., community ties through phone contact and visitation) also exhibit lower rates of violent misconduct. There is no personality testing profile consistently associated with prison violence.

Criminal history has a complex relationship with inmate misconduct and violence. A prior prison sentence is associated with a greater frequency of misconduct and violence. A history of violence in the community, however, has neither a simple nor an intuitively obvious relationship with prison violence. The rate of prior violent arrests has not been consistently demonstrated to be associated with serious or assaultive prison misconduct. Prior arrests for assault and current convictions for robbery and/or assault are associated with an increased risk of prison violence, but not with prior or current homicides. A current conviction for a sexual assault has an inverse relationship with prison violence, while prior arrests for sexual assault have no relationship.

Sentence length has a counterintuitive relationship with prison misconduct and violence. It would be expected that inmates facing very lengthy sentences, and particularly those serving life without parole, would have higher rates of prison violence as a result of their more serious offenses of conviction and because they have *nothing to lose* (i.e., far distant or no parole). Inmates serving lengthy sentences, including those serving life without parole, however, tend to have lower rates of prison misconduct and violence.

Long-term inmates appear to be particularly motivated to maintain the small privileges and incentives (e.g., commissary, recreation, visitation) that make their confinement less loathsome.

Equally contrary to intuitive expectations, the seriousness of the offense of conviction is not a good predictor of prison violence. Convicted first-degree murderers have been observed to have lower rates of disciplinary infractions and equivalent rates of assaultive misconduct of all severities as compared to property offenders or inmates in general. Capital offenders sentenced to life terms have very low rates of serious prison violence as well. Because it is very difficult to predict a low base rate behavior, the infrequency of serious violence among capital offenders has critically important implications for future violence as a death-sentencing consideration. Neither mental health experts nor capital juries have demonstrated the ability to reliably identify which offenders will perpetrate serious violence in prison or make predictions that improve over the underlying base rate. As a result, only predictions of an improbability of future serious violence enjoy high accuracy rates.

The most startling evidence of the absence of a trajectory from conviction offense to prison misconduct comes out of the Missouri prison system. Since 1991, Missouri has *mainstreamed* its capital punishment or death-sentenced inmates, intermingling them among the general population of a high-security prison rather than segregating them on a super-maximum death row. The capital punishment inmates are celled and programmed with inmates serving nondeath sentences. A 25-year retrospective examination of their prison disciplinary histories finds a low and not disproportionate rate of serious or assaultive misconduct. This finding raises serious questions regarding the security rationale used to justify the highly restrictive, solitary, segregated confinement typifying death rows nationwide.

Caution Regarding Case-Specific Application

An important caution is warranted in making case-specific applications of the correlates of prison misconduct and/or violence. Because of the very low base rate of serious prison violence, even a factor demonstrated to generalize across jurisdictions that is strongly associated with increased risk may

still reflect a decided improbability. To illustrate, if a factor was associated with a 3-fold higher incidence of serious violence, but the base rate of such violence is only .01, inmates reflecting that factor would still have a very low incidence (.03).

INSTITUTIONAL VIOLENCE AND MISCONDUCT, ASSESSMENT AND MANAGEMENT OF

Effective assessment and management of institutional violence and misconduct generally begin with effective theory. The three most popular

theories of institutional violence and misconduct are the deprivation model, the importation model, and the three models (control, responsibility, and consensual) that make up John DiIulio's administrative management theory. This entry provides an overview of each theory or model, followed by a review of associated assessment and management issues.

Theory

Deprivation Model

The deprivation model of inmate behavior holds that the rigid, coercive, and punitive conditions found in jails and prisons are responsible for institutional violence and misconduct. Gresham M. Sykes discussed the *pains of imprisonment* which he believed were brought on by deprivations in five areas: autonomy, security, access to goods and services, freedom of movement, and heterosexual relationships. In the face of these *pains of imprisonment*, some inmates violate prison rules in an effort to overcome the deprived state created by incarceration as well as to get some of their needs met. According to the deprivation model, inmates adapt to the rigid and coercive conditions of prison by forming an inmate subculture designed to shield them from the harsh realities of prison life. The act of being socialized into the subculture of prison, a process known as *prisonization*, and adoption of the inmate code and its associated value system, in turn, lead to prison violence and misconduct.

Importation Model

Dissatisfaction with the deprivation model led to the creation of the importation model of inmate behavior. According to John Irwin and Donald Cressey, the creators of the importation theory, prison violence and misconduct stem from characteristics that inmates, upon entering prison, bring with them from the streets. This is another way of saying that institutional violence and misconduct are the result of preincarceration characteristics and experiences. Proponents of importation theory note that inmates who were leaders on the street also tend to be leaders in prison and that inmates who were violent on the streets also tend to be violent in prison. Gangs are a major problem

in prisons in that core gang members contribute disproportionately to prison violence and misconduct. Congruent with the importation theory, inmates who were affiliated with gangs on the streets also tend to be affiliated with gangs in prison. Like the deprivation model, the importation model emphasizes subcultural values, but in the case of importation these values are believed to have predated the individual's prison experience.

Administrative Management Theory

Whereas the deprivation and importation models emphasize inmate actions, patterns, and adaptations, administrative management theory emphasizes prison managerial styles. According to this perspective, prison managerial styles can be organized into three distinct models. The *control* administrative management model uses remunerative (reinforcement) and coercive (punishment) controls to manage inmate behavior while stressing formal and professional relationships between staff and inmates. The *responsibility* administrative management model, by contrast, deemphasizes formal control, highlights inmate responsibility, and promotes informal staff-inmate relationships. The *consensual* administrative management model, a hybrid of the control and responsibility models, provides for greater flexibility than the control model and greater oversight than the responsibility model. Research indicates that the control and consensual models generally produce the most orderly run institutions and the lowest levels of inmate misconduct and violence.

Assessment

Deprivation

Professionals operating out of the deprivation model ordinarily assess deprivation by examining the physical and psychological characteristics of the institution where the individual resides. One of the first factors to be reviewed by professionals interested in conducting a deprivation analysis is institutional security level, given that deprivation grows and the inmate code strengthens as one climbs the correctional security ladder toward higher levels of institutional control and security. Professionals interested in conducting a

deprivation analysis may want to consider each of the five *pains of imprisonment* (i.e., autonomy, security, access to goods and services, freedom of movement, and heterosexual relationships) because while prisons are depriving by nature, some prisons are more depriving than others, particularly when it comes to security, access to goods and services, and freedom of movement. Rating each of the five *pains of imprisonment* on a simple 4-point rating scale (1 = *low*, 2 = *moderate*, 3 = *high*, 4 = *very high*) may be of some assistance in conducting a deprivation analysis of various correctional environments.

Importation

There are a number of variables and assessment devices that can be used to assess importation factors. Static risk variables such as age, criminal history, substance abuse history, marital status, and prior gang affiliations and dynamic risk variables such as current peer associations, criminal thinking, self-control, and antisocial personality processes make it possible to assess importation on a case-by-case basis. Instruments can also be used to assess importation, provided they contain a sufficient number of relevant static and dynamic risk factors—the Level of Service Inventory–Revised, Lifestyle Criminality Screening Form, Psychopathy Checklist–Revised, the Self-Appraisal Questionnaire, Psychological Inventory of Criminal Thinking Styles, and Criminal Sentiments Scale–Modified, among others. Assessment by way of importation is designed to evaluate an individual’s preincarceration status with respect to factors such as prior criminal history, substance misuse, peer associations, personality, cognition, and demographics (e.g., age) for the purpose of assessing the person’s odds of engaging in institutional violence and misconduct. Research indicates that importation factors do, in fact, predict institutional adjustment, particularly when more serious forms of disciplinary infraction are examined.

Administrative Management

The eight features or dimensions proposed by DiIulio as a way of differentiating among the control, responsibility, and consensual models can

also be used to assess managerial style. The first dimension, formalness of organizational communication, assesses a prison’s chain of command and level of paramilitary organization. The second dimension, formalness of personal relations, offers insight into the interactions between staff and between staff and inmates. The third dimension, formalness of inmate/staff communication, examines the extent to which inmate/staff communication is strictly professional. The fourth dimension, staff discretion, can be considered an index of how much leeway staff members are given in the performance of their duties and in their dealings with inmates. The fifth dimension, regimentation of inmate lives, probes the degree to which inmate behavior is monitored and routinized. The sixth and seventh dimensions, response to inmate rule violations and response to inmate disruptiveness, are an estimate of how much emphasis a prison places on inmate obedience. The eighth dimension, inmate participation in decision-making, assesses the level of inmate involvement in correctional decision-making.

Management

Deprivation

One way to manage institutional violence and misconduct for those operating from a deprivation perspective is to address the variables that give rise to deprivation. This can be accomplished by focusing on the five *pains of imprisonment*: autonomy, security, access to goods and services, freedom of movement, and heterosexual relationships. Autonomy and freedom of movement are by definition restricted in prison. As such, there is not much that can be done to alleviate these forms of deprivation. Security, access to goods and services, and heterosexual relationships, on the other hand, may be more amenable to intervention. Prisoners who feel safe are less likely to be violent and less apt to turn to prison gangs for protection. Hence, creating a safe environment through effective staff supervision, enhanced security, and the use of electronic surveillance (e.g., cameras) is vital in managing the deprivations of prison life. Second, certain goods and services, to include conjugal visits, could be made more available to inmates in exchange for good behavior. Third, although based largely on

anecdotal evidence, coeducational prisons appear to have fewer episodes of violence and misconduct than male-only institutions, perhaps by providing a more normalized environment.

Importation

Whereas importation may best be assessed with static risk factors, it is probably best managed with dynamic risk and needs factors. Criminal thinking, for instance, has been found to mediate the relationship between static risk factors and prison violence and misconduct. Moreover, it possesses incremental validity relative to common static risk factors such as age, race, criminal history, prior substance misuse, and gang affiliation in predicting institutional violence and misconduct. Peer associations are another dynamic risk or needs factor that should be taken into account when constructing a program of prison inmate management. Interventions designed to reduce criminal thinking and discourage antisocial peer associations, neither of which is easily accomplished in a prison setting, could be of assistance in eviscerating the importation variables known to support institutional violence and misconduct. There is, in fact, research to suggest that targeting a large number of criminogenic (i.e., crime-causing) needs in an intervention is significantly more effective in decreasing violence and institutional misconduct than targeting only a few criminogenic needs in an intervention.

Administrative Management

Each of the eight dimensions that differentiate among the control, responsibility, and consensual models of administrative management theory could be used to create policies for improved management of institutional violence and misconduct. By making organizational communication more formal and having clear lines of authority, correctional officer stress and displaced frustration could be reduced and their effect on inmate discipline and violence minimized. Clearly defined roles and relationships between staff and between staff and inmates have also been found to promote a positive emotional climate in jails and prisons. Where inmate/staff communications

are formal, yet sufficiently flexible to address legitimate inmate issues and concerns, institutional violence and misconduct are usually low. Giving staff a fair amount of discretion and latitude in the performance of their duties has also been found to contribute to diminished levels of institutional violence and misconduct. Regimentation, coupled with a certain amount of flexibility, has been found to have a calming effect on inmates, while weak monitoring of prisoner behavior and lack of routinized patterns within a correctional facility have been found to contribute to inmate unrest. Handling inmate discipline in a way that is both fair and flexible and managing inmate disruptiveness in a firm and consistent manner are also important in promoting inmate discipline and reducing institutional violence and misconduct. Finally, permitting inmates a reasonable degree of involvement in some of the decisions that affect their everyday lives can foster an attitude of investment that helps lessen inmate discontent and associated levels of violence and misconduct.

INSTITUTIONAL VIOLENCE AND MISCONDUCT: VIOLENCE TOWARD OFFENDERS

Violent victimization of inmates is a long-standing problem in prisons worldwide. This entry provides an overview of institutional violence toward offenders, which is defined as instrumental (proactive) or expressive (reactive) aggression directed at jail, prison, or other inmates by either fellow inmates or correctional employees. Instrumental violence fulfills an ulterior motive (e.g., manipulation, intimidation, or dominance), whereas expressive violence occurs in response to a negative emotional state (e.g., anger, fear, or frustration). Physical injuries need not occur to satisfy this definition of institutional violence; in fact, sexual victimization of inmates, which may not even involve physical contact between the victim and perpetrator, is a major concern for correctional administrators.

Prevalence and Modus Operandi

Homicide rates in correctional institutions have displayed a downward trend over the past few decades; in 2000, only 51 inmate-on-inmate homicides (less than 0.1 per 1,000) occurred in U.S. state or federal prisons. Inmate-on-inmate physical assaults, however, are much more common. In 2000, 28 inmates of every 1,000 in state or federal prison were physically assaulted by another inmate. Studies outside the United States also show high levels of victimization.

Both male and female inmates are far more likely to experience physical victimization than those in the general population. Research indicates that younger inmates and inmates with mental health problems are at a particular risk for assault victimization. One obstacle to understanding the rate of offender victimization is underreporting. There are several reasons for this, but one primary reason is a strong norm in prison culture against *snitching* or informing on a fellow inmate.

Causes

Deprivation and Importation Theories

There are two prevailing theories posited to explain inmate-on-inmate violence. The deprivation

model holds that prison, as a total institution, is a closed-off environment in which new inmates are quickly socialized. The various *pains of imprisonment* create feelings of degradation and powerlessness, which cause inmates to behave aggressively. Thus, the variables of interest for violence include security level, segregation measures, staff-to-inmate ratio, crowding, racial composition, and amount of programming. Prisons with a high degree of social control by staff and elevated security levels have more instances of misconduct, including inmate-on-inmate violence.

The other model, importation, argues that inmates have already been socialized outside of prison, and they bring these attitudes, beliefs, and behaviors with them to the institution when they are incarcerated. Thus, the impetus for violence comes from already-learned behaviors rather than from a process of prisonization. This model looks to offender characteristics, such as socioeconomic class, age, race, and past criminal history. Younger inmates are more violent, as are male inmates, but studies looking at race have shown mixed results. Gang affiliation, in addition to a prior history of violence, appears to be another key factor. Some research has blended the two major theories, arguing that inmates with high existing levels of aggression are more affected by deprivation factors and thus commit more assaults against other inmates in their presence.

Expressive and Instrumental Factors

Personal factors associated with institutional violence against inmates can be classified as either expressive or instrumental. Expressive violence is an attempt by the individual to discharge the tension created by negative emotions (e.g., anger, depression, and frustration). Examples of expressive violence include retaliating against other inmates for perceived insults or threats and emotional outbursts following the loss of freedom and degradation that inmates experience upon being confined.

Instrumental violence involves an attempt by the individual to use aggression to achieve a goal other than the release of tension. Inmates may use violence or threats of violence to manipulate other inmates or gain power within the prison system. They may also employ violence to enforce gang

dominance, punish displays of disrespect from other inmates, or protect themselves from assaults, preemptively or in self-defense. While expressive violence views aggression as an end unto itself (e.g., a reaction to a negative affect), instrumental violence views aggression as a means to an end (e.g., a display of power over another inmate).

Prevention

Increasing the staff-to-inmate ratio by hiring more personnel and training all employees in emergency response procedures can reduce inmate-on-inmate violence. Increasing surveillance through the use of direct supervision and adding cameras to eliminate blind spots are additional ways to complement correctional officer presence. Whereas supermax facilities may reduce inmate-on-staff violence, they appear to have no effect on violence between inmates. Proper classification of inmates can also reduce violence by reducing contact between highly predatory inmates and minimally experienced inmates. While increasing staff presence, training staff to communicate better with inmates, and improved inmate classification all contribute to decreased violence among inmates, simply reducing overcrowding has not been found to have much impact on inmate-on-inmate violence.

Better prison management is another way to reduce institutional violence. This includes educational, psychological, and vocational programming that adequately addresses offenders' needs and decreases idle time for inmates. Teaching offenders to manage negative emotions and mentally cope with prison life can also serve to reduce inmate-on-inmate violence. Decreasing gang influence and providing better mental health services are additional ways to reduce institutional violence, although policies that favor the incarceration of the mentally ill or lead to inadequate screening of inmates for mental illness, gang affiliations, and prior institutional violence need to be reevaluated.

Staff-on-Inmate Violence

Staff-on-inmate violence also occurs and has received a fair amount of attention, particularly

with respect to the sexual victimization of offenders. Female inmates comprise a greater percentage of victims of sexual predation than male inmates although sexual victimization is a problem with both sexes. Male staff members are more likely to be accused of perpetrating sexual offenses against inmates than female staff, although sexual predation by staff is clearly not restricted to male staff. Of particular concern to correctional administrators is the fact that close to half of all reported sexual assaults on inmates in one large-scale study were allegedly committed by staff, although this includes sexual harassment as well as crimes such as rape.

Glenn D. Walters and Erica Yurvati

INSTITUTIONAL VIOLENCE AND MISCONDUCT: VIOLENCE TOWARD STAFF

Institutional violence can be directed at a number of targets, including government and personal property, other inmates, staff, and oneself. This entry provides an overview of institutional violence directed toward staff, which is defined as

instrumental (proactive) or expressive (reactive) aggression directed at jail, prison, or other correctional personnel. Instrumental violence is aggression performed as a means of achieving some ulterior goal (e.g., manipulation, intimidation, or dominance). Expressive violence is aggression performed in response to a negative emotional state (e.g., anger, fear, or frustration). Staff victims of institutional violence include correctional officers, case managers, administrators, and anyone other than an inmate who is employed in a correctional facility. Physical injuries need not be sustained in order to satisfy this definition of institutional violence.

Prevalence and Modus Operandi

The results of a 1999 survey revealed that over 2,400 correctional workers in the United States required medical attention following an assault by an inmate. Although this number represents less than 1% of all staff who work in U.S. correctional institutions, it does not include the much larger portion of staff who were assaulted without serious injury. What this indicates is that while serious assaults on correctional staff are relatively rare, they do occur and that over the course of a 20- or 30-year career a correctional worker has a good chance of being assaulted at least once by an inmate. The assault may not require medical treatment, but it can be distressing nonetheless. How the assault is carried out varies based on a number of factors but is most often the result of an inmate pushing, hitting, punching, or kicking the correctional worker with his or her hands or feet. More serious assaults tend to involve the use of an improvised weapon such as a blunt force instrument (e.g., pipe or *lock in a sock*) or homemade knife (commonly referred to as a *shank* or *shiv*). In some cases, the assault is carried out by spitting or throwing an object or a substance (e.g., water, urine, or even feces) at the correctional worker.

Causes

Situational Factors

There are several situational factors that may promote institutional violence against staff. Prison overcrowding is one such factor. It makes intuitive sense that overcrowding would encourage both inmate-on-inmate and inmate-on-staff violence by

creating a tense correctional environment. Much of the research, however, does not support this hypothesis. In fact, several studies have found just the opposite—that is, that a greater density of inmates in jails and prisons is associated with a reduced rather than an increased level of inmate-on-inmate and inmate-on-staff assaults.

Prison management is another situational factor that can lead to institutional violence. The results of research on the management–violence relationship are more consistent than the results of research on the overcrowding–violence relationship and indicate that failed prison management is often associated with inmate-on-staff violence. Inconsistent or lax application and enforcement of institutional rules and regulations, high staff turnover, security breaches, and lack of discipline among correctional officers are all signs of a breakdown in prison management.

Institutional violence against staff can also arise from conflicts between specific inmates and staff members. The manner in which a staff member handles a potentially volatile situation can, in fact, have a strong bearing on the situation's outcome. A conflict or potential conflict is less likely to escalate into violence if staff members remain calm, treat inmates with respect, and are fair and consistent in applying the rules than if they project anger or agitation, talk down to inmates, or act in a prejudicial or an arbitrary manner.

Personal Factors

Personal factors associated with institutional violence toward staff and other inmates can be classified as either expressive or instrumental. Expressive violence stems from such negative emotional states as anger, fear, and frustration and is an attempt by the individual to discharge the tension created by the negative emotion. Inmates frustrated by the outcome of an unfavorable parole board hearing or incensed by an officer who they feel is deliberately antagonizing them are at risk of engaging in expressive violence toward staff.

Instrumental violence involves an attempt by the individual to use aggression to achieve a goal other than the release of tension. As a case in point, an inmate may use the threat of violence to intimidate or manipulate staff or employ physical

or verbal aggression against staff to gain the respect of other inmates. Unlike expressive violence, where aggression is an end unto itself (i.e., to reduce tension), instrumental violence considers aggression as a means to an end (i.e., to manipulate, intimidate, or dominate).

Prevention

Having a large complement of staff members capable of responding to emergencies protects both staff and inmates against violence. The Federal Bureau of Prisons has a policy in which all staff members are considered correctional workers first. As such, all staff members, not just correctional officers, are expected to respond to emergencies. This provides a maximum response without increasing the size of the correctional officer complement. Eliminating blind spots and installing cameras in areas where blind spots cannot be eliminated have also been found to reduce institutional violence. The use of super-maximum institutions has no apparent effect on inmate-on-inmate violence but has been found to reduce inmate-on-staff violence.

Another way institutional violence can be reduced is with better prison management. Good prison management also entails reducing inmate idleness by providing them with meaningful educational, psychological, and vocational programming. Training staff to effectively communicate with inmates can diminish prison violence by lowering inmate-staff conflict and related incentives for violent behavior. Finally, beyond staff simply keeping inmates busy, evidence-based programming designed to teach inmates stress management and coping skills can reduce institutional violence against staff by instilling in inmates the ability to self-manage their own behavior.

INTENSIVE SUPERVISORY PROBATION

Policy shifts away from the use of incarceration in response to prison overcrowding have resulted in increased numbers of offenders being supervised in the community. A number of responses have been developed to help provide agencies the tools they need to handle this increase. One of these responses is intensive supervisory probation (ISP), a supervision protocol in which probationers are managed under more restrictive requirements than those employed for lower risk probationers.

There are several terms that are used to refer to the subject of this entry. These include, but are not limited to, *intensive probation supervision*, *intensive supervision probation* (or parole) (ISP), and *intensive supervision programs* (ISP). For consistency and clarity, this entry refers only to *intensive supervisory probation*, though the term applies to both probation and parole supervision, as well as to similar programs operating under alternate names.

Regardless of the designation, ISP was developed primarily to save money and to increase public safety; research conducted since the mid-1980s questions whether these and other goals are being met. Despite this, many agencies continue to employ ISP as a method of managing higher-risk offenders. This entry provides an overview of the history and development of ISP, as well as a brief summary of current research in this area of community corrections.

Probation Supervision in the United States

Community supervision is a key element of the current correctional landscape. Due to prison overcrowding and financial concerns, there has been an increase in the general use of community-based supervision for many types of offenders, and it represents an increasingly common form of social control. The prevalence of community supervision is clear: According to the Bureau of Justice Statistics, as of 2015, about 4.6 million adults were under some form of community supervision, which amounts to approximately one in 53 adults in the United States.

Two distinct forms make up community supervision—probation and parole. With probation, offenders are remanded directly to the custody of the community supervision agency, either as an independent sentence or after the completion of an incarceration term. Parole occurs when an offender is released from prison before completing the full sentence and is permitted to serve out the remainder of time in the community and under the supervision of a parole agency. Probation and parole exist at the federal, state, and local levels, though their exact characteristics vary by jurisdiction. Despite these differences, both probation and parole are used as a way to release or divert offenders from prison while keeping them under formal supervision until their sentences are finished.

In response to the increasing number of individuals under supervision, as well as increases in the potential dangerousness of those offenders, probation agencies have developed supervision strategies to respond to the resulting challenges. ISP is one common option that provides a control-based approach focused on small caseloads and increased reporting requirements.

ISP Programs

ISP programs have five primary goals: (1) to increase public safety by preventing recidivism; (2) to reduce correctional costs by shifting offenders away from incarceration; (3) to reduce prison or jail populations, also by releasing offenders to community supervision; (4) to serve as an intermediate punishment, a sanction of a level of severity that falls between that of incarceration and traditional probation supervision; and (5) to facilitate

the provision of treatment to offenders. The extent to which these goals are prevalent, or their relative importance, varies by jurisdiction.

There are two general types of ISP: prison diversion and probation enhancement. Each approach has a distinct goal. In the case of prison diversion, ISP is used to place offenders who would have otherwise been sent to prison onto community supervision. Probation enhancement, on the other hand, results in the application of stricter conditions for certain types of offenders, often those considered more serious, than they would have received on routine probation. These characterizations are not mutually exclusive.

Thus, there is not one specific definition of ISP. Instead, ISP serves as an umbrella term to describe many types of institutional responses characterized by stricter supervision protocols for probationers. Although there is a significant degree of variation among programs, ISP protocols often focus on offenders believed to be at a high risk, either due to an increased likelihood of recidivism or due to the presence of a particular criminogenic need. Despite this diversity, many ISP programs share common traits.

Office Visits

ISP offenders are often expected to meet with their officer on a regular basis, often much more frequently than offenders under standard conditions of supervision (e.g., weekly compared to monthly). These meetings can take place at the probation department, a regional office, or other location.

Home Visits

Often conducted by a probation officer along with armed law enforcement officers, ISP programs may require additional contacts between officers and probationers outside of the office. These visits often take place at the offender's residence, where probation officers in many jurisdictions are permitted to conduct limited searches without a warrant and are in addition to the increased office meetings that characterize ISP. In some programs, probation officers also visit offenders' places of employment or school to verify participation or attendance.

Drug Testing

Under ISP protocols, offenders are required to submit to urinalysis screening with increased frequency. These tests provide information about an offender's recent substance use, a clear prohibition for individuals under community supervision. In some jurisdictions, only ISP offenders (and those with a court order) receive drug testing, while in others all offenders are tested, with the ISP program requiring more frequent screening (e.g., once a month vs. biannually).

Employment

In order to facilitate reintegration, as well as the payment of any fines or restitution, some ISP programs require that probationers obtain legal employment while under supervision. Those offenders who cannot obtain a job are required to document their attempts to do so.

Treatment

Though dependent upon the resources available, many ISP programs require probationers to participate in some form of treatment. In some cases, all ISP participants must enroll, while in others only those probationers with a demonstrated need (e.g., drug addiction) must attend. The availability, nature, and quality of programming vary significantly between jurisdictions and, as discussed later in this entry, are likely major contributing factors to the effect of ISP programming.

Zero-Tolerance Policies

Especially in the case of supervision-focused ISP programs, many protocols are characterized by a lack of tolerance toward rule-breaking of any kind. While this obviously includes committing a new crime (*direct violation*), it may also include infractions of the rules of community supervision (*technical violation*). This latter group may include, for example, positive drug tests for illegal substance use or failing to show up to a scheduled office visit. An ISP offender may be revoked for a single positive test, while an offender under standard supervision may be given a second chance. While many officers have discretion as to which

violations they pursue in court, this component of ISP allows probationers to have their supervision revoked, resulting in reincarceration, for a wider range of behaviors than would be the case for offenders under more standard or traditional models of community supervision.

Development of ISP

The approach to community supervision that would become known as ISP began in the 1960s. Earlier programs, prior to ISP, allowed departments to allocate their own resources but without a strong focus on reducing recidivism. At that time, it was believed that ISP could facilitate smaller caseload sizes, and in turn, the increased correctional officer-probationer contact would lead to lower recidivism. Accordingly, early ISP models emphasized community reintegration, encouraged behavioral change, and facilitated treatment. ISP was not initially intended to serve as a sanction for higher risk or noncompliant probationers. Research on these programs, however, highlighted that this approach to ISP reduced neither recidivism nor technical violations, and as a result, ISP fell out of favor for several years.

ISP returned to the forefront of correctional management in the 1980s, though with a revised focus. This generation of ISP supervision, spearheaded by programs developed in Georgia and Florida, focused on using ISP as an opportunity to divert offenders out of, or away from, incarceration. This required a philosophical shift within the programs themselves, with supervision and control supplanting treatment facilitation as the primary aim. In some cases, these ISP programs were developed specifically to approximate the levels of oversight possible in prisons, but with the inmate residing in the community and being supervised by the much lower-cost probation department. As was the case in earlier generations, research on the effects of ISP failed to identify the intended, positive effects of the program. In this instance, ISP was found to encourage high rates of returns to custody for technical violations, in effect offsetting much of the cost-saving and diversionary effect of the programming.

By the early 1990s, a series of studies, conducted at several sites across the country, provided rigorous evidence of the negative effects of

control-focused ISP. This research strongly suggested that increasing the intensity of community supervision alone did not have an effect on subsequent crime, and at the same time, strict rules and zero-tolerance policies increased the number of technical violations, returns to incarceration in prison or jail, and absconding, a negative event when a probationer fails to attend required meetings or respond to contacts and which results in a warrant being issued for the offender's arrest. However, these studies suggested that when treatment and employment support were integrated directly into ISP, there was the potential for an increased rate of successful program completion.

Risk, Needs, and ISP

The research on ISP programs with only increased supervision suggests that these programs are ineffective. However, these control-focused ISP programs can serve as the foundation for delivering other programs that have been shown to be effective. For example, correctional programs that incorporate cognitive and behavioral skills training into community supervision have been associated with reductions in offending. ISP, unlike routine supervision with less frequent contact requirements, offers agencies the chance to deliver such treatments.

For ISP programs, as well as correctional interventions more generally, research suggests that the most effective allocation of supervision and treatment resources follows the Risk-Need-Responsivity model. For ISP, there are three key elements. First, the risk principle states that offenders with higher risk, as assessed using a reliable and valid actuarial risk assessment instrument, should receive higher levels of supervision. An appropriate risk level is determined by assessing both static and dynamic factors linked to reoffending. Static factors do not change and include gender, criminal history, and age at first arrest. Dynamic factors can be changed through treatment and may include substance abuse, learning deficiencies, and antisocial behaviors. Therefore, ISP should be reserved for probationers who are statistically likely to commit a new, serious offense. Second, the need principle requires that supervision addresses the offender's specific risk factors for criminal behavior, which are

referred to as criminogenic needs. Knowing an offender's individual needs allows for treatment to be tailored, such that only the services that are the most beneficial are required (and so an offender without a need will not participate in irrelevant programming). Lastly, the responsivity principle involves ensuring that an offender receives treatment and supervision in an appropriate manner.

Conclusion

ISP offers policy makers and correctional officials the opportunity to tailor the characteristics of community supervision to the underlying offense and relative level of risk of each offender. While these are acceptable policy goals, research has shown that ISP increases the amount of control over, and monitoring of, offenders and is not only unlikely to reduce successful probation completion or future offending, but in many cases, it increases the rate of probation revocations, an undesirable outcome. However, ISP, when combined with programming focused on addressing the criminogenic needs of the individual offenders, can play a role in the modification of behavior and prevent recidivism. While developing a successful, cost-effective, intensive, community-based supervision protocol is possible, it requires more than simply ratcheting up levels of control. ISP as one protocol is the most effective when used in conjunction with risk and needs assessments, treatment and rehabilitation, as well as punishment and surveillance.

INTERNATIONAL APPROACHES TO CRIME PUNISHMENT

The questions concerning appropriate courses of action to reconstruct a viable polity in the aftermath of events that have included genocide or other forms of mass atrocity comprise one of the most perplexing dilemmas of the contemporary era. In dealing with past crimes, what remedies will best foster a healing process for the deep societal wounds inflicted by civil wars, mass uprisings, or other government policies? Considering the nature of atrocities during the late 20th and early 21st centuries in areas such as Afghanistan, Bosnia, Cambodia, the Democratic Republic of the Congo (formerly Zaire), Rwanda, Sierra Leone, Sudan, and Syria, what course of action will promote a general opinion that justice has been served in ways that establish a clear break with the past? Strategies must balance the individual psychological needs of victims in terms of providing support, redress, and closure with broader future goals that encompass necessary steps to move the society as a whole toward reconciliation and forgiveness. Balancing the desire for vengeance by victims against the fear of a general

program of retribution by the general public requires a remarkable exercise of political will and wisdom in a climate where, as in Rwanda and Kosovo, hatred may still form a significant backdrop for victims and perpetrators alike.

This entry provides an overview of international approaches to crime punishment, particularly as they relate to mass atrocities and human rights abuses such as the Holocaust or other genocides. Beginning with a discussion of strategies and goals in the aftermath of such incidents, the entry continues with an examination of what is involved in implementing trials and transitional justice measures such as truth commissions.

Strategies and Goals

After World War II, the reaction to the Holocaust ignited a firestorm of activity focusing on developing international regimes to protect human rights. In addition to the International Military Tribunal, under Control Council Law 10, the Allies held 12 trials at Nuremberg that ostensibly dealt with war crimes. Because the term *genocide* had not yet entered into the legal lexicon, many of the charges comprised crimes against humanity as defined in the London Charter of the International Military Tribunal. In 1948, the United Nations General Assembly adopted the Universal Declaration of Human Rights, which served as the foundation document for future treaty law, and states quickly negotiated and adopted the Genocide Treaty. The Genocide Treaty envisioned an international court to try cases. However, that provision remained a dead letter for almost 50 years until the creation of the ad hoc tribunals and the establishment of the International Criminal Court (ICC) in the wake of the conflicts in Bosnia and Rwanda in the 1990s.

Trials as the appropriate strategy for dealing with past incidents of mass atrocity and mistreatment appeared to be a preferred choice, but the tumultuous events of the late 1980s and early 1990s also generated another movement that has had a considerable impact. While various conflicts and their associated events garnered center stage, a considerable number of autocratic/despotic regimes changed to democratic forms of government. The new regimes in states such as Chile, Guatemala, and South Africa also faced the issue

of how best to deal with the excesses of previous governments. The trend generated many suggestions for alternative approaches to deal with the problems and inadequacies of trials as sole solutions. Based on the proposition that victims of massive human rights abuses have a right to know the truth and to receive reparations, alternative approaches emerged under the collective label, *transitional justice*.

Transitional justice encompasses a hybrid approach that primarily involves nonjudicial measures to redress legacies of massive human rights abuses. In theory, through an emphasis on victims' rights, if correctly organized and implemented, transitional justice will promote civic trust and support for the institutions of a democratic rule of law. The chief methods used to implement transitional justice strategies are commissions of inquiry, commonly referred to as truth commissions, authorized to conduct official investigations into past patterns of abuse. The process may incorporate trials but not as the primary method of establishing responsibility for transgressions.

Trials

Advocates argue that trials provide an important historical function by investigating, examining, and illuminating the details of cases as well as dispensing a rough justice, particularly to the leaders, planners, and organizers regardless of their position. A by-product is the positive impact on advancing the cause of international human rights through the interpretation of substantive law as well as the development of appropriate process. The International Criminal Tribunal for the former Yugoslavia (ICTY) asserts that it has provided thousands of victims the opportunity to be heard and to speak about their suffering. Critics argue that the judicial process is ill-suited to deal with questions of justice and reconciliation that arise in the wake of either a large-scale incident (e.g., Rwanda) or a long-standing pattern of discrimination and abuse. Moreover, in the aftermath of such an upheaval, local justice systems may lack the will, resources, and administrative support to conduct investigations and protect witnesses. Personnel may lack both the motivation and skills to mount successful cases. The most cogent criticisms focus on the perceived

limitations of the judicial process itself: inflexibility, scope, and the costs and time necessary for trials.

First, critics point out that the process of reconciliation requires sensitivity to situational nuances that trials cannot provide. In particular, lawyers and judges operate by methods of fact determination and processes that differ significantly from those used by politicians and diplomats. The legal process has the goal of producing outcomes according to a standard set of procedures that presumably will produce comparable decisions in related cases. Courts require proof adduced through the application of a very strict set of rules. Such proof may not always be readily available considering the murky circumstances that often surround violent conflicts. For example, in 2011, due to the lack of evidence, the ICC had to withdraw the indictments or end the trials of six high-profile Kenyans that included President Uhuru Kenyatta.

Political leaders and diplomats look for viable solutions that fit the specific situation as they see it at the time—the *art of the possible*. Their craft depends upon flexibility in finding the right strategy to deal with a situation to produce a politically acceptable outcome. When the Security Council debated setting up the ICTY, many diplomats expressed misgivings about the impact of possible indictments on the peace process that eventually produced the 1995 General Framework Agreement for Peace in Bosnia and Herzegovina (also known as *the Dayton Accords*) because the individuals essential to implementing the agreement were also the individuals most likely to be indicted. Nonetheless, the ICTY prosecutor proceeded to issue indictments, regardless of the political consequences. The 2009 ICC indictment of President Omar Bashir (Sudan) has raised similar issues with respect to Darfur.

Second, judicial systems are not equipped to handle a large volume of cases in a timely manner. The sheer scale of genocidal crimes involving thousands of killers can overwhelm almost any judicial system, but what tribunal could hope to punish all of the guilty or impose an appropriate sentence for those who planned and facilitated genocide while promoting a general feeling that justice has been done? In the aftermath of the 1994 Rwanda genocidal campaign, jails held

130,000 accused, far beyond the capabilities of any justice system to prosecute in a timely manner. Although national courts prosecuted a larger number, during its 20-year life span (1994–2014), the International Criminal Tribunal for Rwanda dealt with a total of 93 cases; 75 of these actually went to trial.

Third, trials by their nature seem an extraordinarily awkward, slow, and expensive way to deal with the types of problems presented by genocide and mass atrocity. At its peak, the ICTY employed 1,200 people. These included 18 permanent judges and a number of judges *ad litem* (temporary) to help move the workload forward. The ICTY indicted 161 individuals. The trial of Slobodan Milošević, the first ever of a sitting head of state, had just entered its *fifth* year when his death in 2006 ended proceedings.

Fourth, in terms of retributive justice, what sentence or series of sentences could possibly appropriately balance the scale when guilt involves death and injury to thousands? We tend to think in terms of domestic criminal law systems where the idea that, in some measure, the law applies penalties proportionate to the crime. Yet the crimes of the worst serial killers seem insignificant in comparison with genocide and crimes against humanity. The deeds of those responsible for the appalling level of atrocities in Rwanda or Cambodia mock the ideal of appropriate punishment. European Community courts and all international courts may not impose the death penalty. As of 2017, the ICTY and International Criminal Tribunal for Rwanda have been reluctant to hand out life sentences. Still, given the age of many defendants, these may equate to a life sentence.

Truth Commissions

Archbishop Desmond Tutu, who chaired South Africa's Truth and Reconciliation Commission, briefly summarized the theory behind alternative strategies. He asserts that the best strategies must originate from within, not from the outside. Simply, those who have suffered have to decide what is best for them. Arguments for commissions of inquiry also emphasize the ideas of fairness and due process. If prosecutions are part of the process, they will focus on those who committed the most barbarous acts. Advocates argue that

commissions of inquiry and limiting prosecutions to the few directly responsible for specific acts, while avoiding the attribution of collective guilt to the entire population, will establish an impartial historical record and provide victims with a sense that their grievances have been addressed.

In theory, truth commissions reach more people directly in that the process requires involvement and dialogue at the grassroots level rather than often remote judicial hearings. As cogent as this may sound in humanitarian terms, these processes can be as slow as, if not slower than, judicial hearings and involve some of the same problems. Because of hardened attitudes, incidents of mass atrocity and genocide, such as in Kosovo and Rwanda, produce perceptions of winners and losers. Practically, seeking to overcome those attitudes to engender a genuine dialogue has its pitfalls. Beliefs often do not change, and psychological wounds do not heal easily. The ultimate evaluation will depend upon two factors: the willingness of individuals to come forward to speak and how a government deals with the findings of the commission. Given that the goal is to reach as many victims and others with knowledge of events, the number of witnesses and hearings may consume considerable time and expense. Sheer numbers may preclude more extensive investigations into individual cases.

Foremost among obstacles is establishing the trust necessary to have people come forward. Resource constraints often make witness protection programs problematic or nonexistent. Those involved have a high motivation to destroy any evidence of their complicity and often still remain committed to the cause. Targets will include witnesses and those perceived as *collaborators*. In Northern Ireland, 10 years after the Good Friday Agreement, individuals who attended local meetings aimed at promoting reconciliation between local groups of Catholics and Protestants received death threats.

The impact also depends on how governments then respond to the findings. The difficulties of moving forward in the aftermath of such upheaval require a resolute political will to tackle sensitive cases that involve high-profile instigators or other participants who may still have a following. Programs of amnesty at the local level, often enacted by a still-corrupt

regime, have sought to preclude investigation and prosecution. In some countries, the assassinations of judges and prosecutors and others who have sought to move beyond the violence seemed to have dampened the zeal to investigate, let alone punish. The final assessment of truth and reconciliation projects remains to be seen, as does the long-term impact of the ad hoc international courts and that of the ICC.

INTERNATIONAL APPROACHES TO CRIME REDUCTION

The pursuit of crime reduction is not the exclusive preserve of action by governments. Rather, it requires finding a balance between the protective efforts of individual citizens (and households) and collective action by government, from the local to the national or federal level. For some types of crime, such as cross-border trafficking, it may

require international collaboration between countries through entities such as the International Criminal Police Organization or the United Nations Office on Drugs and Crime. Policies to reduce crime can be aimed at dissuading individuals from being willing to commit crime (*individual prevention*), at making crime more difficult to commit (*social prevention*), or at some combination of the two. Crime prevention programs may aim to discourage children and young people from becoming involved in offending, for example, while the installation of car alarms or door locks may *harden targets* and make theft less likely.

Approaches to crime reduction differ from country to country, as what constitutes a crime and is therefore subject to criminal law varies from place to place as well. Additionally, the pattern of crime within a country as well as the priority attached to reducing particular types of crime can also vary. In some countries, the relationship between religion and criminal law is more blurred than in Western democracies, and this influences both the substance of *crime* and the institutional methods for its control and reduction. It follows that variation is to be expected when considering such international contexts of crime reduction policy. This entry focuses on crime reduction approaches, primarily crime reduction projects and programs, as well as the role of governmental agencies and citizens in reducing crime.

Role of Governmental Agencies

Responsibility for that part of crime reduction that is funded from public sources generally falls on a country's criminal justice system. This involves a range of agencies including a court service, prosecution service, defense service, police force, offender management services, and judiciary. The service providers include public authorities, voluntary and charitable sector organizations, and commercially operated, profit-driven enterprises.

Beyond the criminal justice system, then, many other agencies have an important role to play in crime reduction. The provisions of education, housing, and social services, for example, may all have an important influence on individual attitudes to crime and on the propensity to offend.

The effectiveness of the agencies responsible for crime reduction policy depends on the quantity of

resources made available to them, the clarity of policy objectives, the quality of cooperation among agencies, and the type of incentive structures embedded in the contracts for service delivery.

Role of Citizens

Irrespective of public provision, there remains a key role in crime reduction for the potential victims of crime not only from private citizens but also corporations and other organizations. There are many steps citizens can take in an effort to reduce the likelihood of becoming a victim of crime. This ranges from direct crime prevention measures such as locking the doors and windows of cars and houses to indirect strategies such as choosing safer routes when traveling or avoiding rowdy bars.

For corporations, fraud or theft of goods by employees can be just as significant a drain on a firm's profits as theft by customers in a retail outlet. Reliance on public prevention is unlikely to be sufficient, so firms employ a wide range of methods to reduce their exposure to criminal loss, including employee monitoring, account auditing, security guards, patrols, private closed-circuit television (CCTV) systems, steel window shutters, alarms, and many more.

Crime Reduction Projects and Programs

In most countries, there will, at any instant, be a variety of initiatives and projects in operations designed to reduce particular types of crime or offending. Some of the crime reduction efforts may be based on legislative change, for example, a change to the structure of penalties for those convicted of offenses. Other efforts may be based on experimental interventions or projects that may be a part of a wider, concerted crime reduction program. Some of these projects, particularly those based on prevention and aimed at younger children, may be seeking longer-term effects on offending. Others, such as tackling substance abuse, may have much shorter horizons.

Individual Offending and Reoffending

There is a consensus that reducing individual offending has to take account of a variety of risk

and protective factors. Interventions aimed at children and young people attempt to prevent these populations from becoming involved in offending in the first place and to that end target the following: poor behavioral control; deficits in social cognitive ability; emotional problems or distress; antisocial beliefs and attitudes; exposure to violence and conflict in the family; being a victim of abuse; low intelligence quotient; involvement with drugs, alcohol, or tobacco; and treating attention-deficit/hyperactivity disorder or learning disorders.

The probability of an individual convicted of an offense to be reconvicted subsequently has been found to be associated with employment and accommodation status prior to previous imprisonment, drug use and criminal history, drug use since release, and receiving additional punishments while in prison. These findings underpin the host of projects aimed at preventing individuals from becoming offenders or reoffenders. Many have been evaluated in some way, but reliable international evidence derived from well-designed trials to test the effectiveness of such projects remains hard to find.

Situational Crime Prevention

Other approaches to crime prevention focus on reducing the likelihood of becoming a victim of crime, often via a mixture of private and public efforts. For example, the likelihood of a house being burgled may be reduced by steps taken both by the owner (e.g., having a dog, installing an alarm) and by the local government (e.g., funding police patrols, street CCTV systems). In the context of offenses taking place in international venues, such as with piracy, an international naval presence (funded by several national governments) can operate in conjunction with protective measures adopted on individual ships (e.g., more lookouts, anti-boarding devices).

Evaluating the effectiveness of these *target-hardening* measures in reducing crime is just as challenging as assessing the impact of offender-oriented prevention efforts. For example, installing a CCTV system in one parking lot in a small town may simply displace thefts from cars in that location to a nearby parking lot not covered by CCTV. This does not mean that CCTV systems

are ineffective. It means that a wider view has to be taken when taking and assessing the impact of installations.

Contents of Programs

Crime reduction projects vary widely in their content. To give an indication, they may include the following:

- initiatives with children and young people such as Sure Start programs, mentoring, and activity-based projects with a focus on an area such as sports, music (or other arts), and environmental work
- target hardening, based on the design of products and spaces, the installation of alarms and CCTV, uses of automatic number plate recognition, gates, bolts and locks, and the provision of antipersonnel deterrence in the form of sprays, alarms, and whistles
- increased numbers of police and/or the provision of more equipment such as Tasers, guns, communication devices, vehicles, forensic science, and crime scene investigation technology
- heavier sentences in the form of larger fines, longer terms of imprisonment, and community service in an effort to provide greater deterrence and incapacitation effects
- greater emphasis on offender rehabilitation in prison and probation settings
- Measures to address substance abuse in an effort to break the link between alcohol misuse, abuse, and violence against the person and between drugs and acquisitive offenses
- measures to reduce social deprivation or exclusion, such as Sure Start programs to improve life chances and reduce the likelihood of becoming an offender
- measures to address mental illness, the incidence of which is much higher among offenders
- offense-oriented activity such as efforts to intercept drug shipments or people trafficking

Measuring Crime Rates and the Impact of Crime Reduction Policy

There is rarely any completely reliable measure of the underlying volume of crime from which to

assess change. Events recorded in police crime statistics will typically be an underestimate of crimes committed as many events will not be reported to the police or will not be recorded. A fall in the number of crimes as recorded by the police will therefore usually be an underestimate of a true reduction achieved.

A more reliable method is to conduct a large-scale, properly randomized survey of the experience of crime as reported by respondents. A proportion reporting having experienced, say, a domestic burglary within the previous 12 months, is then used to make an estimate of the total number of burglaries that have taken place. A comparison of this year's estimate with that of the previous year provides a measure of whether crime reduction has been achieved. Where similar surveys such as the International Crime Victimization Survey have been conducted across several countries, trends can be compared internationally. More often, however, the issue is whether a particular intervention or pilot has been effective. To estimate the size of crime reduction effects, well-designed project evaluations are required, ideally based on the kind of experimental trial methodology utilized by scientists, medical researchers, and others.

Evidence of Program Effectiveness and Cost-Effectiveness

In a 1997 study of intervention effectiveness by L. W. Sherman, findings included the following:

- Community-based programs to address youth violence are more effective when they concentrate resources in high-risk areas, whereas programs for recreation, mentoring, and the advertising of crime prevention are ineffective. From family-based programs, there is strong evidence that intervening at the adolescent stage with high-risk youth in high crime areas is less effective than intervention earlier, at the preadolescent stage. Parent-training strategies have been shown to be effective in improving protective factors with these younger groups. There is evidence that school-based programs are effective in preventing crime if schools have sufficient organizational capacity. Programs for communicating and clarifying norms and for teaching self-control are effective.

- Adult employment programs aimed at older male ex-offenders appear effective but do not work with youth violence. Investment in human capital, based on developing job skills, does not reduce crime. There is some evidence that place-based (situational) programs can be effective, but the scientific quality of these studies is rarely very high.
- A number of police practices are effective in preventing crime, including putting extra police resources into high-crime *hot spots*, having police units that focus on serious repeat offenders, and proactive enforcement of drunk driving laws. By contrast, practices that are unlikely to prove effective include increased random patrols of beats, more rapid response to emergency calls, neighborhood watch, arrests of juveniles for minor offenses, arrest crackdowns at drug markets, and community policing that is not focused on known risk factors.
- Offender management programs are generally effective when based on a therapeutic community treatment of drug-using offenders in prison; keeping frequent, serious offenders in prison; and structured rehabilitation programs reflecting risk factors. By contrast, programs shown to be ineffective include correctional military-style boot camps, fear-based approaches such as *Scared Straight* and shock probation, and community-based alternative sanctions that do not have a treatment element, such as intensive supervised probation, and community residential and juvenile wilderness programs.

Cost-Effectiveness

For purposes of comparing benefits from public spending on crime reduction with returns from other programs, such as defense or education, the analysis should be extended to account for costs. Assessing in monetary terms the costs and benefits of projects or interventions provides evidence on the rate of return on crime reduction projects for comparison with the returns from competing public investment programs.

INTERNATIONAL CRIMINAL POLICE ORGANIZATION (INTERPOL)

The European Revolution of 1848 (alternately known as the *Spring of Nations* or the *Year of Revolution*) brought about the emergence of INTERPOL. It is an international organization that monitors transnational crimes across the globe and facilitates international police cooperation. This entry discusses the history of INTERPOL, its structure, and its global role in law enforcement.

European Revolution of 1848

The European Revolution was a general discontent among the masses due to a widespread decline in traditional authority in which over

50 countries were involved. Among the leading countries of the revolution were France, Denmark, Austria, Hungary, the Netherlands, Germany, Italy, Poland, and Russia. In all of the countries, pivotal to the uprisings were people's dissatisfaction with political leadership, agitations for freedom of the press, need for individuals' participation in government and democracy, desire for humane treatment of workers, and high waves of the spirit of nationalism. Then came coalitions of weak reformers, middle-class individuals, and blue-collar workers who rose against the absolute monarchies and authoritarian political leaders. Tens of thousands of the revolutionaries were killed, and many others were forced into exile.

The unhealthy situation led to intra-European terrorism and assassination of political leaders. Thus, in 1914, a group of politicians, lawyers, police officers, and court judges from 14 European countries met in Monaco and held the first International Criminal Police Congress. This meeting lasted from April 14 through 18. Their intention was to establish an international criminal records office to keep track of international criminals and to bring some order and consensus among European nations in law enforcement. This 1914 Monaco Congress failed, however, because it was organized by lawyers and politicians instead of police professionals. A second International Criminal Police Congress was held in New York City in 1922. The 1922 New York City Congress also failed because it drew little international attention.

Emergence of INTERPOL

The plans of the First International Criminal Police Congress to start an International Criminal Police Commission (ICPC) were interrupted by World War I (1914–1918). At the end of World War I, the professional police officials of 21 countries and territories held another International Criminal Police Congress in Vienna, Austria, in 1923. The purpose of this ICPC meeting was to find a way to respond to the enormous upsurge in international crime following the end of World War I. It was at the 1923 Vienna meeting that they established an ICPC.

The participants at the 1923 Vienna meeting wanted police organizations in all continents and

island states around the world to be members of ICPC and invited them to join the international organization. The founding members of ICPC were Austria, Belgium, China, Poland, France, Egypt, Germany, Greece, Italy, and Hungary.

In the design of the organization, ICPC did not want any state control. It simply wanted to be an autonomous international law enforcement coordinator for all member states and remain a nonpolitical organization. From 1923 to 1938, ICPC had 14 meetings as an international coordinator of national police institutions. Its operations were disrupted in 1938 when Adolf Hitler's Nazi Germany invaded, conquered, and annexed Austria. At that time, the capital of ICPC was in Vienna, Austria. On the annexation of Austria, the Nazis moved the capital from Vienna to Berlin, Germany. When the Nazis launched World War II in 1939, it took absolute control of ICPC and managed it throughout the war period from 1939 to 1945. They arrested ICPC president Michael Skubl and incarcerated him (he was rescued when the Allied Forces defeated the Nazis).

After World War II, ICPC was in limbo. In 1946, a Belgian police officer, Florent Louwage, spurred other police officers to restart ICPC. The leading supporters of the Belgian initiative were France, Scandinavia, and the United Kingdom. In this first post-World War II meeting were representatives from both prewar ICPC member states and non-prewar member states. They chose Saint-Cloud, France, as its new headquarters. In 1989, it was moved to Lyon, France, which remains its headquarters.

In 1956, ICPC was renamed the International Criminal Police Organization (ICPO), and ICPO-INTERPOL was chosen as the organization's telegraphic address (often shortened to INTERPOL). INTERPOL began to collect dues from its member countries and also subsisted on gifts and investments.

Internal Organization

INTERPOL's roles and operations are clearly defined by the general provisions of its constitution. The ICPO-INTERPOL Constitution was adopted in 1956 by the General Assembly at its 25th session held in Vienna, Austria.

General Provisions

Article 1 through Article 4 of the ICPO-INTERPOL Constitution outlines the organization's General Provisions. It provides that the official location of its operations shall be in France. The purpose of the organization is 2-fold. First, it is to promote mutual assistance among all criminal police units, within the limits of member countries' laws, and in the spirit of Universal Declaration of Human Rights. Second, it is to establish institutions that will contribute to the prevention and suppression of ordinary crimes. INTERPOL forbids itself from taking any part in political, military, religious, or racial issues. Member states can delegate police officials whose duties fall within the activities of INTERPOL. Countries that want to be members of INTERPOL can request to do so through the Secretary General of the organization. Membership must be approved by a two-thirds majority of INTERPOL's General Assembly.

Organizational Structure

The ICPO-INTERPOL Constitution outlines the organization's structure and roles. These include the General Assembly, Executive Committee, General Secretariat, National Central Bureaus, INTERPOL Advisers, and the Commission for the Control of Files.

General Assembly

The supreme authority of INTERPOL lies in the General Assembly. It is made up of delegates from member states of INTERPOL. Each state can be represented by one or more delegates but must have only one delegation head, who is appointed by a competent authority in the country. Given the technical nature of INTERPOL, states are advised to include among its delegates high-level officials from government departments dealing with police matters, officials whose duties are connected with those of INTERPOL, or government officials who have a specialty in the agenda of the particular INTERPOL session or conference.

The General Assembly carries out duties as specified in INTERPOL's Constitution, specifically in Article 8. It sets out ground rules and suitable

means to reach the organization's objectives, approves program activities for each year prepared by the Secretary General, and determines other necessary regulations. The General Assembly elects individuals to carry out certain duties, adopts resolutions, and makes recommendations to member states on issues that INTERPOL is competent to make. It also forges the financial policy of INTERPOL and approves agreements with other organizations.

Member states are required to carry out the decisions of the General Assembly. The General Assembly is expected to meet every year in an ordinary session and may meet in an extraordinary session at the request of the Executive Committee or the majority of the member states. During any session, the General Assembly is empowered to set up special committees to handle particular issues. It can decide to hold regional conferences between two General Assembly sessions.

In General Assembly deliberations, only one delegate from each member state has a right to vote. Decisions are made by a simple majority, with the exception of situations when the Constitution specifies a two-thirds majority.

Executive Committee

INTERPOL's roles are piloted by an Executive Committee of 13 members. It is chaired by the president of INTERPOL. The Executive Committee is made up of the president, three vice presidents, and nine delegates. The 13 members of the Executive Committee are required to come from different countries, and global distribution of the members is duly expected. A term on the Executive Committee is for 3 years, and delegates are not immediately eligible for reelection to the same posts.

The Executive Committee makes sure that the General Assembly's decisions are carefully carried out. This body prepares the agenda for sessions of the General Assembly. It initiates programs and projects it deems necessary and submits them to the General Assembly. It supervises the duties of the Secretary General, and it exercises all powers and authority delegated to it by the General Assembly.

Delegates to the General Assembly session elect the president and the three vice presidents from

among themselves. For the election of the president, specifically, a two-thirds majority is required. If the two-thirds majority is not obtained after the second ballot, a simple majority will be deemed expedient. The president of INTERPOL presides over the meetings of the General Assembly and those of the Executive Committee. It is the president's responsibility to see that INTERPOL's activities conform to the decisions of the General Assembly and Executive Committee. The president is required to convene a meeting of the Executive Committee at least once a year and be in constant communication with the secretary general of INTERPOL.

General Secretariat

The General Secretariat is a permanent administrative department of INTERPOL, headed by the Secretary General. It includes the Secretary General, as well as technical and administrative staff.

The Executive Committee nominates the Secretary General and submits his or her name to the General Assembly, who can then approve the nomination for a 5-year term. The Secretary General, chosen from among persons who are highly experienced and competent in police matters, is the chief administrative officer of INTERPOL. He or she directs the staff, prepares the organization's annual budget, and organizes and directs INTERPOL's permanent units according to the orders of the General Assembly or Executive Committee.

The Secretary General submits all proposals and projects concerning INTERPOL to the Executive Committee. This individual is responsible for the Executive Committee and the General Assembly. The Secretary General participates in the discussions of the Executive Committee, the General Assembly, and other dependent bodies of the organization. The Secretary General, in the execution of his or her duties, represents INTERPOL and not his or her country of origin.

The Secretary General and his staff are prohibited from soliciting or accepting instructions or orders from any government or authority outside of INTERPOL. They are to abstain from any activity that may prejudice their international responsibilities. Member states are prohibited from taking any action to influence the Secretary General and his or her staff in the discharge of

their duties and are required to assist them in the execution of their duties.

National Central Bureaus

INTERPOL discharges its functions through National Central Bureaus. One of the mechanisms it uses to achieve its mission and speed up communication and cooperation among its members is the establishment of the National Central Bureau in each member state. These bureaus are staffed with highly trained and experienced law enforcement officers and are established to help member states in the prevention and control of transnational crimes in their localities.

INTERPOL Advisers

INTERPOL has a board of advisors whom it consults in some scientific matters and other matters related to crime prevention and control. These individuals are appointed for a term of 3 years by the Executive Committee, contingent upon the approval by the General Assembly. They are chosen from among persons who have proven reputations in fields of interest to INTERPOL operations.

Commission for the Control of Files

The commission for control of files is made up of five members appointed for a term of 3 years. This is an independent entity for processing personal information to confirm that individuals are complying with the rules and regulations established by INTERPOL.

INTERPOL Treasury and Resources

INTERPOL's operating budget comes from financial contributions of its member states. Second sources of revenue include gifts, bequests, subsidies, grants, and other resources. The Executive Committee must approve and accept any secondary sources of revenue. This is to avoid receiving gifts from organizations that could inject corruption into INTERPOL.

Scope of INTERPOL Operations

INTERPOL's primary aim is to support its member states' police services in their fight to prevent crime and execute criminal investigation effectively. In this

venture, with the cooperation of the National Central Bureaus, INTERPOL speeds up cross-border police cooperation and assists the organizations and authorities whose mission is to prevent and control crime of all types. To achieve its aim, INTERPOL carries out its activities in four core functions:

- secure global police communications services
- operational data services and databases for police
- operational police support services
- training and development

Secure Global Police Communications Services

International police cooperation is built on constant adequate and successful communication. INTERPOL observed that successful global law enforcement goal requires a strong network of speedy communication. In effect, INTERPOL capitalized on modern advanced information systems and designed a state-of-the-art global communications system for law enforcement society. This system is called *I-24/7*, which stands for *INTERPOL-24 hours a day, 7 days a week*.

Operational Data Services and Databases for Police

The second core service of INTERPOL is operational data services and databases for police. INTERPOL developed a broad range of global databases that incorporates important information, such as names of criminals and suspected persons, fingerprints, photographs, deoxyribonucleic acid profiles, requests for wanted persons, lost and stolen travel documents, stolen vehicles, and weapons related to criminal cases. These types of information keep transnational criminals nervous about engaging in some international crimes because they increase the chance of being caught.

Operational Police Support Services

Operational Police Support Services is INTERPOL's third core service to member states. The word *support* here simply means that member states can make use of INTERPOL's expert knowledge in law enforcement. Through the national

central bureaus and regional offices, INTERPOL responds quickly to the needs of its members. This led to development of emergency support and operational activities based on the member states' priority crime areas, be it drugs and organized crime, terrorism and public safety, fugitives, human trafficking, or financial and high-tech crimes. Additionally, support services include collection, analysis, and evaluation of information received from member states by INTERPOL's headquarters. INTERPOL also extends support to its member states by sending police officers with special law enforcement skills to investigate sites.

In fighting terrorism, INTERPOL uses the following forms of notices:

- **Red Notice:** This signifies seeking the arrest of a wanted person, with a view to extradition. This notice may serve as a provisional arrest warrant depending upon the country involved.
- **Blue Notice:** This is used to collect more information about a person's location, identity, and/or illegal activities in relation to a criminal matter. This notice enhances the identification of a terrorism suspect.
- **Green Notice:** This is used to provide criminal intelligence about persons who have committed criminal offenses and are likely to repeat the crimes in other countries. This notice is an alert signal for calling attention to criminals.
- **Orange Notice:** This is used to warn police, related security entities, and other international organizations of possible threats from hidden weapons, parcel bombs, and other dangerous items or materials, such as those that can be used in a terrorist attack.

Training and Development

Finally, INTERPOL's fourth core service is Training and Development. This division of INTERPOL's goals functions and plays a significant role in overall mission of the organization to achieve international police cooperation. This Training and Development division of INTERPOL's goals helps member states to improve their law enforcement skills and strategies.

INTERPOL is always helping member states to improve their police training in their own institutions. Additionally, INTERPOL provides various

transnational crime-fighting techniques to all member states, international law enforcement organizations, and its United Nations partners.

INTERNATIONAL EXTRADITION

International extradition is the primary legal process by which one country responds to the request of a second country to send (extradite) suspected criminal offenders to face criminal charges in the second country. The person who is extradited (sometimes referred to as the *fugitive* or *relator*) may have fled the jurisdiction of the second country in an effort to avoid prosecution. Increasingly, however, the alleged offender has not fled and instead faces charges that arise out of his or her conduct in the first country and that had effects in the second country. Every year, executive and judicial authorities in scores of countries collectively request the extradition of hundreds of people to face criminal charges. In the United States, federal prosecutors bring slightly more than 100 extradition requests to court per year on behalf of

countries seeking extradition of an alleged offender. This entry explores the basis by which extradition occurs. Beginning with an examination of the legal authority for extradition, the entry continues with a discussion of traditional components of extradition law (i.e., circumstances by which it occurs and the particulars of treaties) and conditions by which extradition may be defended (i.e., human rights violations and the ways this defense may occur) and ends with a brief discussion related to the alternatives to extradition.

Legal Authority for Extradition

In general, a country obtains the authority to extradite from two sources: its own internal or domestic law or a treaty relationship with the country that requests the extradition. Internal law is sufficient to provide authority to extradite, but a country's internal law may also require a treaty relationship. International law does not require countries to agree to an extradition request without a preexisting commitment to do so. A country may choose, but is not required, to extradite a person to another country as a matter of international comity. Thus, some countries will extradite without a treaty, based on reciprocity—the assumption being that the other state will reciprocate by honoring similar requests for extradition.

Some authorities hold that an international law duty to extradite exists for *jus cogens* crimes (crimes that violate fundamental international law norms). Any such obligation, however, overlaps in practice with multilateral conventions, such as the Convention Against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment, that nearly every country has signed and that require signatories either to extradite or to prosecute people who violate the provisions of those conventions (*aut dedere aut judicare*).

Regional conventions or agreements may also impose extradition obligations or their equivalent, as with the Council of the European Union's (EU) decision to abolish extradition within the EU and replace it with the European Arrest Warrant. Despite these various multilateral arrangements, however, most extraditions take place pursuant to the terms of bilateral extradition treaties.

In addition to the obligations imposed by a convention or a treaty, the internal law of the

extraditing country will typically determine the authority, process, and limits that apply to extradition. Those requirements will sometimes be complex. Depending on the specific country, its internal law of extradition will integrate constitutional, statutory, administrative, and/or judge-made law. Historically, judicial and political authorities have each had a part in the extradition process.

Traditional Components of International Extradition Law

Many countries (including China, France, Germany, Israel, Mexico, and Russia) refuse or reserve the right to refuse to extradite their own citizens, as a matter of their internal law. Extradition treaties involving these countries will usually acknowledge this position. Under the European Arrest Warrant, by contrast, a country cannot refuse to execute a warrant for one of its own citizens, although it can request that its nationals be returned to serve their sentences in their home country. The internal law of the United States does not prevent the extradition of its nationals, and the U.S. Supreme Court has declared that whether a U.S. citizen can be extradited to another country turns on the language of the relevant extradition treaty.

The extradition treaty between the United States and Mexico, signed into force in 1978, provides an example of the way countries address nationality. The treaty simultaneously recognizes Mexico's refusal to extradite its nationals and the willingness of the United States to extradite its nationals:

Neither Contracting Party shall be bound to deliver up its own nationals, but the executive authority of the requested Party shall, if not prevented by the laws of that Party, have the power to deliver them up if, in its discretion, it be deemed proper to do so.

To be extraditable, a person must have committed an offense that falls within the terms of the relevant treaty. Some treaties contain a list of specific offenses that qualify for extradition. Others refer to categories of offenses. Many modern extradition treaties take a broad approach and allow extradition for conduct that is criminal under the law of both countries. Traditionally,

nearly all countries have required *dual criminality*—that the conduct at issue be criminal in both countries, even if the specific crimes are not entirely the same. The modern approach of allowing extradition for conduct that is criminal under the law of both countries essentially adopts dual criminality as the only standard for extradition.

Extradition proceedings also involve factual issues. The usual approach, often reflected in treaties, is for the extraditing country to determine whether the factual record provided by the requesting country provides probable cause to believe that the extraditee committed the offenses charged. The extraditing country will hold a hearing on this issue, but it will not hold a trial, and it will not make a formal or informal finding of guilt. The person facing extradition may not even be allowed to present evidence that contradicts the proof provided by the requesting country. Thus, the U.S. Supreme Court has held that the extraditee may not introduce evidence that would establish the defense of insanity.

The EU has adopted a different approach to factual issues for extradition among its member states. Under the European Convention on Extradition and, more recently, the European Arrest Warrant, the requested person has the right to a hearing, but the nature or amount of evidence is not a factor to be considered in refusing to extradite or execute a warrant.

Defenses to Extradition

Most extradition treaties include provisions that forbid extradition of a person who already has been tried for the same crime. International law provides some general support for these treaty provisions, but there is no clear international law rule on this topic. Treaties that include this protection fall into two general categories. Some refer to prosecution for the same *acts*, while others refer to prosecution for the same *offenses*. The protection offered by the word *acts* is broader and more fact-based, and the protection offered by *offenses* is more narrowly focused on the elements of the crimes. The Council of Europe's framework decision for the European Arrest Warrant limits execution of a warrant if another EU state has reached a final adjudication of the requested person *in respect of the same acts*.

Extradition treaties usually will specify whether the statute of limitations is a defense to extradition. If this defense is available, the treaty will also specify whether the relevant statute of limitations is that of the extraditing country, the requesting country, or both.

Since the late 1800s, extradition treaties usually have included clauses that bar the extradition of people who committed *political offenses* and who had, it was assumed, fled the requesting country to escape political persecution. Recently, however, the political offense exception has come under pressure because a robust political offense exception could prevent extradition of people involved in terrorism.

Although most treaties include a political offense exception, it usually appears without a definition, with the result that opinions written by national courts are the primary source of doctrine. Case law tends to distinguish between *purely* political offenses (e.g., treason and sedition) and *relative* political offenses or offenses *of a political character* (e.g., murder committed in the course of a rebellion). Both types of political offenses usually qualify as a defense from extradition. Many recent treaties, however, prevent the application of the political offense exception to crimes of terrorism that otherwise might qualify as *relative* political offenses or that would require courts to distinguish relative political offenses from mere politically motivated crimes. Another category of offenses consists of crimes committed because of political motivations. These crimes do not fall within the political offense exception.

The status of the conduct as a political offense (usually a defense from extradition) and the political motivations of the extraditee (not a defense from extradition) are distinct from the political motivation of officials in the requesting country. Allegations that the extradition is politically motivated will not support the political offense exception.

Extradition and Human Rights

In theory, the extradition process accommodates both the legal and the political aspects of extradition. Courts address objective legal questions about the specific charges and the sufficiency of the evidence, while political authorities handle subjective political and diplomatic questions about the

desirability and ramifications of extradition. Human rights claims complicate this division of labor.

Traditionally, a person facing extradition cannot introduce evidence in court that the requesting country will mistreat him or her in some manner. Mistreatment is a broad category that ranges from unfair procedures, to squalid prison conditions, to torture or other forms of deliberate abuse. The justification for this rule of noninquiry is that the political and diplomatic authorities of the extraditing country have decided to allow extraditions to the requesting country and that those authorities have the discretion to consider case-by-case claims of potential mistreatment. In countries that follow the rule of noninquiry, these issues are resolved through *diplomatic assurances* that the extraditee will not be mistreated.

Outside the United States, and particularly in Europe, the rule of noninquiry has eroded. International law, in the form of the Convention Against Torture, the Convention Relating to the Status of Refugees, and the Convention Against the Taking of Hostages, forbids extradition if the extraditee would face torture or persecution. Although it is possible to satisfy these requirements through diplomatic assurances, this duty falls to the courts in some countries.

In Europe, the European Court of Human Rights has ruled that the European Convention on Human Rights forbids extradition if there are substantial grounds for believing that the extraditee will be subjected to torture or other cruel, inhuman, or degrading treatment or punishment in the requesting country. That court has also held that national courts in Europe must review the actions of executive officials to ensure compliance with this rule of inquiry.

By contrast, the noninquiry doctrine remains strong in the United States. Some U.S. courts have suggested that an exception to the noninquiry rule exists for particularly severe mistreatment, but no U.S. court has ever relied on this potential exception to forbid an extradition. The U.S. Congress has declared that no one should be extradited if there is a substantial risk of torture, but it has also bolstered the rule of noninquiry by stating that U.S. courts do not have jurisdiction to address this issue. The result is that the United States continues to rely on diplomatic assurances for compliance with its international law obligations in this area.

Specialty

The rule or doctrine of *specialty* provides a separate potential defense, not to the extradition itself but to the criminal proceedings in the requesting country. Specialty requires the requesting state to prosecute the extraditee only for the crimes that supported the extradition request (or for lesser included offenses) and to respect any conditions or limitations that the extraditing country placed on the extradition. Note, however, that the requesting state can ask the extraditing state for permission to impose additional charges or to depart from any conditions or limitations. The extraditee also has the ability to consent to additional charges or to departures from conditions or limitations. Many treaties explicitly incorporate specialty, and some authorities assert that it has the status of customary international law.

Alternatives to Extradition

Extradition provides a procedural mechanism for international cooperation in the area of criminal justice, but extradition is not the only method for securing the presence of an alleged offender. Extradition treaties will not necessarily forbid other, less formal efforts, and the U.S. Supreme Court has ruled, for example, that if an extradition treaty “does not prohibit [the defendant’s] abduction . . . the court need not inquire as to how [the defendant] came before it” (*United States v. Alvarez-Machain*, 504 U.S. 655, 662 (1992)). Arguably, however, international human rights law forbids such conduct.

Another alternative to extradition is deportation or removal pursuant to national immigration law. Although deportation is similar to extradition because it results in the expulsion of a person from the territory of a country, it does not in theory take place at the request of another country, and the person facing deportation may have a right under national or international law not to be sent to the country that has initiated criminal proceedings.

INTERNATIONAL EXTRADITION, FOUNDATIONAL CASES OF

International extradition is the primary legal process by which one country responds to the request of a second country to send (extradite) suspected criminal offenders to face criminal charges in the second country. Although statutes and treaties form the backbone of extradition doctrine, court decisions have played a critical role in defining the circumstances in which extradition can take place and the roles that different political actors or institutions can play in the extradition process. This entry focuses on several 20th- and 21st-century court decisions from the United States, the United Kingdom, the European Court of Human Rights, and the International Court of Justice (ICJ). Each of the cases also considers and discusses important earlier precedents.

In *Valentine v. United States ex rel. Neidecker*, 299 U.S. 5 (1936), two U.S. citizens asserted that they could not be extradited because the treaty with France did not apply to citizens and the president had no independent power to order their extradition. The U.S. Supreme Court unanimously ruled in their favor, stressed the importance of a clear legal framework for extradition, and limited the president’s authority over extradition.

The Court first declared that, within the U.S. federal structure, “the power to provide for extradition is a national power; it pertains to the national government and to the States.” Second, at the national level, the power to extradite is not an inherent part of executive power:

albeit a national power, it is not confided to the Executive in the absence of treaty or legislative provision. . . . [T]he Constitution creates no executive prerogative to dispose of the liberty of the individual. Proceedings against him must be authorized by law.

Thus, the Court held that extradition proceedings are governed entirely by statute and treaty. Because neither the U.S. extradition statute nor the treaty with France authorized extradition of citizens, the Court rejected the extradition. Subsequent legislation now allows extradition of U.S. citizens when a treaty is silent on the issue, but *Valentine* remains an important statement that extradition is subject to the rule of law and not executive or diplomatic convenience.

Many years later, in *Munaf v. Geren*, 553 U.S. 674 (2008), two U.S. citizens who were detained in Iraq by U.S. armed forces, under the authority of the United Nations–approved Multinational Force–Iraq, brought a habeas corpus petition to challenge their transfer to the custody of the Iraqi government, for trial on various criminal charges. Although the case involved a prisoner transfer, not extradition, the U.S. Supreme Court’s resolution of the case has important implications for the intersection of extradition and international human rights.

Among other things, the petitioners claimed that they were likely to be tortured by Iraqi authorities. The Court responded, “Such allegations are of course a matter of serious concern, but in the present context that concern is to be addressed by the political branches, not the judiciary.” The Court relied on U.S. extradition cases that embrace the *rule of noninquiry*, which holds that U.S. courts cannot inquire into the processes or treatments that await a person facing extradition to another country. Instead, the executive branch bears the primary responsibility for addressing such concerns. The Court noted, however, that “[p]etitioners here allege only the possibility of mistreatment in a prison facility; this is not the more extreme case in which the executive has determined that a detainee is likely to be tortured but decides to transfer him anyway.” Thus, the Court upheld the rule of noninquiry in the United States, but it also signaled that a documented likelihood of torture disregarded by the executive branch might require judicial intervention.

The decision of the European Court of Human Rights in *Soering v. United Kingdom*, 161 Eur. Ct. H.R. (ser. A) (1989), contrasts with *Munaf*. Soering, a German national, sought to prevent his extradition from the United Kingdom to the United States, where he faced capital murder charges in the state of Virginia. In the face of diplomatic requests, Virginia prosecutors adhered to their decision to seek the death penalty. Nonetheless, the United Kingdom approved the extradition. Soering sought review from the European Court of Human Rights, arguing that Virginia’s implementation of the death penalty would violate Article 3 of the European Convention on Human Rights (ECHR), which provides, “No one shall be subjected . . . to inhuman or degrading treatment or punishment.”

The Court agreed:

having regard to the very long period of time spent on death row in such extreme conditions, with the ever present and mounting anguish of awaiting execution of the death penalty, and to the personal circumstances of the applicant, especially his age and mental state at the time of the offence, the applicant’s extradition to the United States would expose him to a real risk of treatment going beyond the threshold set by Article 3.

This decision effectively barred extradition from Europe to the United States in death penalty cases.

Subsequent decisions broadened *Soering* into a general rule that the ECHR forbids its signatories from extraditing or deporting a person to another country if substantial grounds exist for believing that person would be subjected to torture or to a cruel, inhuman, or degrading treatment or punishment. Political officials attempt to comply with this requirement by obtaining *diplomatic assurances* of fair and humane treatment from the requesting country, but the Court has ruled, in *Saadi v. Italy*, No. 37201/06 (2008) ECHR 179, and other cases, that national courts must assess whether those assurances provide “a sufficient guarantee that the applicant would be protected against the risk of treatment prohibited by the Convention.” These cases mandate the sort of inquiry that the U.S. Supreme Court rejected in *Munaf*.

More recently, in *Ahmad and Others v. United Kingdom*, Nos. 24027/07 et al. (2012) ECHR 609, the Court appeared to soften its approach. Upholding the extradition of five suspected terrorists to the United States, the Court rejected the idea that application of Article 3 to application could involve a balancing test, but it also stressed that it has been reluctant to find violations of Article 3 for extradition “to a State which had a long history of respect for democracy, human rights, and the rule of law.”

In *Regina v. Commissioner of Police for the Metropolis and Others, Ex Parte Pinochet* [1999] UKHL 17, the House of Lords allowed Spain’s request for the extradition of former Chilean dictator Augusto Pinochet. Although this decision retreated from an earlier, more expansive ruling, the Lords nonetheless made several significant rulings about the intersection of extradition and international human rights. First, Spain asserted universal jurisdiction to try Pinochet for human rights offenses, and the Lords agreed that Pinochet’s conduct in Chile was criminal under Spanish and English law. Second, the Lords ruled that the United Kingdom’s adoption of the Convention Against Torture did not retroactively criminalize Pinochet’s conduct, with the result that he could be extradited only for acts taken after his conduct became a crime in the United Kingdom. Third, the Lords ruled that Pinochet’s status as a head of state at the time he acted and his subsequent status as a former head of state did not immunize him from responsibility, because the Convention eliminated any such immunity.

The ICJ’s decision in *Questions Relating to the Obligation to Prosecute or Extradite (Belgium v. Senegal)* [2012] ICJ Rep. 422 also considers extradition’s role in human rights enforcement. Belgium claimed that Senegal breached its obligations under the Convention Against Torture by failing either to prosecute or to extradite Hissène Habré, the former president of Chad, for torture and other human rights offenses. The Court agreed that all parties to the Convention may insist on each other’s compliance with the Convention. The ICJ also held that prosecution is “an international obligation under the Convention” and that extradition plays a secondary role, as *an option* that allows a state to “relieve itself of its obligation to prosecute by acceding to an extradition request.”

Collectively, these decisions touch on several distinct aspects of international extradition law. The U.S. and UK decisions apply only within those countries, but the reasoning in those decisions is influential for courts in other countries. The European Court of Human Rights and ICJ decisions, by contrast, provide controlling law for a much greater number of jurisdictions. Each of the decisions also illustrates the tendency for extradition law to overlap with human rights law—sometimes with respect to the rights of the person facing extradition and sometimes with respect to the victims of the crimes that form the basis of the extradition request.

INTERNET EXPLOITATION AND CHILD LURING

Internet (or online) sexual exploitation can cover a range of behaviors with the focus generally relating to adult or youth engagement with child sexual exploitation material and/or the online sexual solicitation of minors, which can include engaging in sexual chat, exchanging sexual material and/or using the Internet to approach a minor to engage in sexual contact. Internet sexual exploitation can involve peers or adults and include luring,

prostitution or trafficking, child pornography, and other forms of sexual abuse. The focus for this entry is *child luring*, also referred to as *online luring* and the *online sexual solicitation of youth*, with an emphasis on adult offenders.

Technology-facilitated communication is an integral and important component of the social worlds of youth from social networking sites to online gaming. With frequent use of these various social media outlets comes greater exposure to others. This includes a greater likelihood of exposure to problematic communications from people who are predatory and/or deceptive regarding their intentions and who use technology to facilitate sexual exploitation or abuse. In survey research, a majority of youth reported experiencing some form of unsolicited or unwanted online sexual communication, much of it from peers. Although most ignore these sexual solicitations, some respond.

This entry begins with a brief outline of laws related to adult engagement of children and youth in sexual solicitations, exchanging sexual images, and making plans to meet for sexual interactions and discusses the prevalence of such behaviors. This section is followed by a discussion of the patterns brought out in recent research on Internet exploitation and child luring inherent to offender and youth behavior. The final points of this entry highlight ways that the Internet can also be a resource in primary prevention efforts for sexual exploitation and child luring.

Laws

Some countries have implemented laws prohibiting adults from engaging children and youth in sexual solicitations, the exchange of sexual images, and plans to meet in person for the purpose of sexual interactions. Generally, the behaviors are considered illegal regardless of who the offender makes online contact with, for example, whether it is an actual child or an undercover law enforcement agent. In some jurisdictions, the online communication does not need to be explicitly sexual. Rather, interactions considered to be related to the grooming of a child (e.g., gaining trust and insight) could fall under online luring or solicitation laws.

Online search software reveals thousands of people looking for child exploitation material at any given time as well as numerous networks of

people actively discussing and participating in the sexual abuse of children. This prevalence corresponds with an increase in the number of online exploitation cases reported to police and child protection agencies. In response, there has been greater professional attention given in this area, a growth in child protection agencies and services, as well as the creation of government agencies to help coordinate responses to these borderless crimes. Additionally, unique collaborative programs have developed from outside government, such as the Thorn foundation, which focuses on technological solutions to these issues.

Research

There has been a steady focus on research relating to Internet exploitation and child luring. National online victimization studies have provided descriptions of offenders and youth, in part dispelling some potential myths regarding offenses and offenders. For example, research has shown that young teens (rather than children) are targeted, that most victims know the offender is interested in sex (e.g., the offender raised the topic of sex quite quickly, engaged in cybersex, transmitted sexual images), and that many victims know the offender is older (e.g., while offenders may lie about their age, many still presented themselves as older). As offenders may search for, target, and exploit specific individuals, such as those with certain vulnerabilities, the research literature has discussed risk factors for youth. These include substance use, truancy, use of online forums expressing dissatisfaction at home or school, and online behaviors such as seeking information about sex and sexual relationships. Many offenders befriend and romance the youth, and consequently, victims may state they felt a close friendship with the offender.

Based on research identifying offense and victim characteristics, some of the conversations around the online sexual solicitation of youth discuss similarities with offenders who have a sexual interest in, or perhaps preference for, pubertal children with some secondary sex characteristics (sometimes referred to as *hebephilia*, as distinguished from *pedophilia*, which refers to a preference for prepubertal children) and the idea these online activities are likely driven by the desire to make contact with children for sexual

activity, compared to other online sexual behaviors such as viewing child pornography. Some discussants have compared these offenders to statutory rapists and suggest those motivated to seek out youth may perceive an online approach as safer and easier than approaching youth off-line; an offender can make contact with a greater number of children, thereby increasing their chance of a (positive) response while believing their risk of exposure to be lower due to the ability to encrypt messages or attempts to mask identities.

Online Resources

While the Internet is related to offending, it also provides additional options for primary prevention efforts as well as additional reporting options and resources for children and their families. For example, luring prevention strategies are available online, along with information about risk factors among youth, and how to recognize potential clues that a child has been approached online. As well, children looking for response options when they receive sexual solicitations or when they feel pressure over sexting requests (requests for sexual chat or nude images) can access advice and resources, including how to get an image removed from the Internet or advice on dealing with cyberbullying and peers. Education about when an action is illegal and how to formally report an offense is also available online.

This area of sexual exploitation and abuse is evolving. Internet and communication technologies will continue to advance and change; hence, the way some online sexual exploitation occurs will also change. Prevention and response efforts will continue to expand. Some will likely focus on the use of technology to identify offenders and identify methods used to offend (and therefore interrupt these methods). Others will involve methods to help triage or prioritize the information received by protection agencies and identify children at risk along with those who have already been victimized.

INTERNET SEXUAL OFFENDERS

Internet sexual offending includes child pornography offending, the sexual solicitation of children and youth (also referred to as *luring*), and the use of the Internet for sexual trafficking and sex tourism (e.g., advertising online). Adults who sexually offend against other adults may also use the Internet to gain information and find targets; however, little is known about adult-against-adult offending. The focus for this entry is Internet sexual offenders, with a specific emphasis on those who offend against children. This entry provides an overview of the prevalence of Internet sexual offending and distinguishes among online, off-line, and mixed tendencies to offend. Reducing or preventing online sexual offending requires collaborative efforts among a variety of sectors as well as an understanding of the nature of both sexual offenses and the offender who engages in these activities. This entry describes these collaborations as well as online and off-line offender characteristics and sexual interests and highlights some of the Internet resources available to both offenders and victims.

With the number of reported cases of online abuse and offending increasing along with greater global access to the Internet, Internet sexual offending is now a global issue. This has given rise to multijurisdictional collaborations in prevention

(e.g., public education, programs for those at risk), interdiction (e.g., reporting, investigating, and interrupting offenses), support for victims, offender management, and research. Among these collaborations are various partnerships involving government, nongovernment organizations, charitable organizations, and academia.

There are some commonly debated questions relating to Internet sexual offenders. For example, whether they represent a new type of offender—one who uses online opportunities to engage with certain content or engage with others in a way they would not do off-line, perhaps because of a lack of knowledge of how to do it or a fear of being caught. Another view is that online offenders are similar to off-line offenders and are merely employing online technologies to facilitate their crimes. In the latter scenario, offenders are motivated to engage in similar behaviors online and off-line. In research examining child pornography and luring, offenders are often grouped based on whether they are *Internet-only* offenders (sometimes referred to as *noncontact* offenders), *off-line* offenders, or *mixed* offenders (those with both online and off-line sexual offenses). A key concern for professionals and the public alike is the relationship between online and off-line offending. What is the likelihood, for example, that an online offender has already, or will in the future, commit an off-line sexual offense?

Child pornography is a common legal name for what may also be referred to as *indecent images*, *child sexual abuse images*, or *child sexual exploitation material*. While child pornography is not a new offense, the Internet has significantly facilitated the accessing and sharing of this material, including the ability to stream sexual abuse in real time. In defining this material, common elements are the type of content included, the age of the depicted children, and the sexual nature of the material. Some countries have specific laws criminalizing the accessing, possession, production, and sharing of these images, which can be in the form of pictures or videos, with a *child* generally defined as anyone under the age of 18 years. The material can depict the direct abuse of a child or depict children in sexually suggestive or explicit poses. It may also be self-produced by children and youth who share sexualized images of themselves with others (these images are then exploited by others).

In some jurisdictions, related material such as text stories advocating or describing sex with children is also illegal and some specify whether the material must include real children (e.g., images involving computer renditions of children may not be illegal). These differences in laws, or a lack of related laws, mean what is illegal in one country may be allowed in another, complicating international efforts to respond to this problem.

Along with child pornography and online sexual solicitation, the Internet facilitates conversations between those with pedophilic and/or hebephilic interests. Sometimes referred to as the *pedophilic subculture*, there are a number of websites, chat rooms, and forums (e.g., GirlChat, BoyChat) where like-minded individuals can discuss adult-child sex, advocate for changes to legislation (e.g., abolish the age of sexual consent), and provide suggestions and advice regarding sex with children. Some groups use specific markers or signs to identify each other and their individual preferences. Depending on the country, this exchange of information regarding sex with children may not be illegal.

Offender Characteristics and Sexual Interests

Child pornography offenders are heterogeneous; those detected span different ages, occupations, educational levels, and social groups. Early research (e.g., mid-2000s) in this area found these offenders, as a group, were more often middle aged, with higher occupations and education; this may reflect access to computers and the Internet and therefore change as the Internet becomes more commonplace globally and as more youth explore sexual interests and sexuality online. Few women are identified as child pornography offenders, a similar finding as for other sexual offenses involving children. Many child pornography offenders have a sexual interest in the material, for example, admitting to masturbating to it or admitting a primary sexual interest in children. Some research has found child pornography offenders demonstrate greater pedophilic or hebephilic arousal in the lab, compared with contact child sexual offenders; offenders with both Internet sexual offending and contact sexual offending against children are perhaps the most likely to be

pedophilic. Involvement with child pornography is used in some assessment protocols as a behavioral indicator of pedophilia. Studies examining the content of child pornography offenders' collections indicate a prevalence of female material, with many having video material and/or text stories describing sex with children. Most also had some adult pornography material and other child images (e.g., nudity or clothed images).

Other reasons given by offenders for accessing child pornography material include novelty-seeking behavior, accidental access, and sexual or Internet addiction; research suggests these are perhaps less common than having a sexual interest in children. There have been somewhat rare examples where the primary motive for having the material, including producing child pornography, has been financial (e.g., running a paid content website). When examining the motivations or pathways to Internet sexual offending, they appear similar to those discussed in the sex-offending literature in general: the importance of sexual motivation (e.g., sexual fantasy and urges) as well as individual differences (e.g., antisocial characteristics).

Research with Internet sex offenders includes the question of overlap between child pornography offending and online sexual solicitation. Not all offenders who sexually solicit children online have child pornography and conversely, not all child pornography offenders will engage in online sexual conversations with children. Online sexual solicitation offenders are described in the literature as often more contact-driven. While they may have child pornography for arousal and masturbatory purposes, they also may use it to *groom* children, for example, to normalize adult-child sexual relations. In research with offenders convicted of child pornography, a minority were known to have engaged in online communications with a child (or an undercover officer posing as a child).

Meta-analytic research comparing Internet sexual offenders (child pornography and solicitation offenders) and off-line offenders suggests those with online-only offenses have greater victim empathy and lower impression management than those with contact sex offenses. Further, those with contact sex offenses demonstrate more cognitive distortions about sex with children and greater emotional identification with children (i.e., children fulfill both sexual and emotional needs).

In addition, contact sexual offenders had greater access to children, more antisocial traits (e.g., lower empathy, higher impulsivity, willingness to violate the rights of others), and fewer barriers to contact sexual offending.

Contact Sexual Offending and Risk Factors

Research has examined the relationship between Internet sexual offending (mostly with child pornography offenders) and contact sexual offending, using both official statistics and offender self-report. This has been done from two perspectives. The first relates to what offenders did until the point of an arrest (usually for child pornography), so this perspective examines offender history and sometimes also the current offense (e.g., an offender may be reported for both a child pornography offense and a contact offense). Part of the concern here is whether an offender identified for an online offense also has sexual contact with child victims, including those not previously identified. Some research, including a meta-analysis, with online sex offenders (mostly child pornography) report approximately half the offenders admitted to a contact sex offense against a child, many undetected or unreported. Numbers for officially reported incidents are smaller, as would be expected since the majority of sexual offending is not reported to police.

The second interest relates to recidivism or the involvement in future incidents, that is, what someone goes on to do after they are identified as an offender: after an interruption, disruption, charge, conviction, and/or after participation in treatment. When considering the risk that an identified offender poses for reoffending, including the type or severity of any new offense, the factors associated with sexual offending in general appear to be relevant—particularly, those dealing with individual differences such as antisociality (e.g., prior offending, failures on conditions of release) and sexual motivations (e.g., sexual interest in children, greater sexual interest in boys). Related to this, there has been significant interest in the development of a risk tool for working with child pornography offenders specifically to triage or prioritize identified or reported cases, to allocate resources and treatment options, for example. To this end, identifying risk factors associated with

sexual offending in general has shown some promise as has distinguishing domain-specific variables, such as the type or characteristics of the child material accessed by the offender.

Methodologies for researching prior and future offending differ, especially in how offenders and offenses are defined and identified. Offender samples may come from clinical or correctional settings or be identified from sex offender registries. Inclusion in the sample may require a charge or conviction for an online sexual offense. When considering how to collect data on offending, access to information can differ widely. When using police reporting systems, for example, there may be no interagency access and therefore offenses in other jurisdictions remain unknown. Further, there are concerns regarding self-report such as the veracity of the information and motivation for admissions. Some recent studies are exploring alternate data collection methods, including online surveys with certain populations including those accessing certain sex-related sites or accessing online help forums or programs. In these instances, individuals self-identify as having offended, regardless of charges, or admit sexual interests in children. All of these methods are broadening our understanding of the relationship between online and off-line offending.

While the Internet can be used to facilitate offending, it also provides alternatives for research and allows for public access to educational and support services. A number of online resources are available for those who are concerned about their thoughts and fantasies about children or have offended in some way. Other sites involve a research component, to further understanding of online sexual offending and offer information for professionals and the general public. The goal is to prevent offending through primary prevention and education (e.g., recognizing and reducing risky or problematic behavior among children and adults), improving responses to offenses, and providing assistance for those who have experienced abuse and for those who have offended.

INTERNET VICTIMIZATION

The Internet has become a virtual playground for criminals. It not only provides new opportunities to commit old crimes but has also led to the creation of new crimes. While some of these criminal behaviors are generic (e.g., hosting or distribution of illicit material, breaches of intellectual property), others target a specific victim. Victimization comes in many forms and can be defined in a number of ways. Researchers debate what constitutes victimization, which behaviors are criminal, and whether crimes and behaviors are distinct or overlapping. Although victimization can be specific, such as those that target children, this entry treats this topic from a general standpoint, focusing on crimes that relate to all victims. Most common among these are malware, fraud, cyberstalking/cyberbullying, and revenge pornography. Each is described in this entry with comments on laws that govern, in a general sense, these types of behaviors.

Malware

Malware can be defined as software that is designed to be hostile or harmful to the user.

Malware exists in a variety of forms, ranging from those that target a general population to those that specifically target an individual. An example of the former would include viruses, which are rarely designed to target an individual as the usual intent is to infect as many computers as possible. However, not all malware acts in this way and some is used to specifically target victims. Perhaps the most notable of this is so-called *ransomware*.

Ransomware, as its name suggests, is a malware that holds ransom a person's computer or device. It could be a general attack (spread through a virus) or a targeted attack. Some ransomware users will browse social media profiles to identify likely victims, targeting a computer via a virus or hack the computer to install the ransomware. The effect of the attack is that a program is installed on the computer that renders it completely inoperable apart from a message that informs the user that the computer is locked and will only be unlocked if payment is made. Usually the computer's contents are encrypted, meaning that bypassing the ransomware is not possible. The consequences of such an attack can be significant. Most people's computers are not just a luxury but are part of their everyday lives. They may have all their important documents stored on it, including pictures and documents crucial to work. While individuals are told to back up data, how many actually do? The trauma may be more significant as it could be accompanied by threats to distribute photographs found on the computer, particularly intimate images or those of their children.

The user then has two options. The first is to refuse to pay, in which case their computer is, in effect, useless. The chances of circumventing the ransomware are minimal at best. A user would have to choose a different computer and accept that the files are gone (unless backed up). The second alternative is to pay the ransom. It may be thought that this would be pointless as the criminals would not give up the key, but in many instances, they do. Their *business model* is premised on people paying, and if the Internet were full of stories of people paying and losing their data, then nobody would pay. However, even if data are recovered, a victim commonly continues to feel victimized and perhaps lost hundreds, if not thousands, of dollars.

Other types of malware that target an individual include hacking into a user's social media profile (which could allow the hacker to bully an individual) or installing spying software (spyware). The latter can be used to take over a computer's function, and there have been reports of individuals using such software to take over the webcam of laptops and tablets, to allow them to view unsuspecting victims while in bed or taking a bath.

Fraud

As with malware, fraud can be general (e.g., a mass e-mail that seeks to trick users into surrendering their bank login details or promising reward for assistance in moving money), but it can also target individuals. Fraud can include, for example, a person posing as a bank employee to an individual or business, claiming suspicious activity on their account. This can throw people off their normal cautious responses as they will be worried they are a victim of crime and therefore more willing to provide Internet passwords and other personal information. Recently, house buyers have been targeted. Criminals hack into their e-mail to identify the likely date of sale and completion (as many lawyers now communicate by e-mail for efficiency). They then send an e-mail purporting to be their lawyer or real estate agent asking them to change the bank details to which the money is sent, diverting the money to a bogus account.

A *new* form of Internet fraud is known as *romance fraud*, which advantages Internet dating sites. A typical case would involve someone meeting online and beginning a friendship. The communication would continue and typically there would be physical meetings, too, as pure online contact would appear suspicious. A romantic relationship will develop and then the fraud will begin. The *partner* may say they are going abroad, and a short time later the victim will be contacted by a *lawyer* to say that the partner has been arrested and has no access to money. Unless money is paid for bail, the partner will be jailed. Alternatively, a *doctor* will say that the partner has been injured but has no insurance. Unless money is paid, the *doctor* will not operate. Such scenarios may seem suspicious, but in the context

of fraud, a person will believe them. They have been told that the partner is abroad and then provided with specific information that correlates. It takes little time to create a website for a fictitious law firm or hospital (so that when the victim checks, it all looks legitimate).

Alternatively, another form of romance fraud involves two people at opposite ends of the country. The romance proceeds, and plans are made for them to move in with each other to the victim's house (there will always be reasons why this is the better choice). The partner then claims not to be able to afford the necessary home alterations to sell her or his own house or not be able to afford the estate agent fees. The victim pays out the money, and the partner disappears.

Romance frauds are lucrative, not least because victims frequently feel too embarrassed to report the crime. While there are few specific laws designed to tackle romance fraud, most existing laws relating to fraud include such types of behavior.

Cyberstalking/Cyberbullying

Cyberstalking, featured in many media and academic writings, is a wide-ranging crime, which can include the digital equivalent to stalking in its traditional sense, with the Internet becoming the vehicle through which a victim is followed. Cyberstalking can include the stalker combing through the victim's social media presence as well as posting information about them to these sites. Cyberstalking can also sometimes be referred to as *cyberbullying*, and there is some debate as to whether these are distinct or related behaviors. The term *cyberbullying* is often used when the victim is a child, though victims can range in ages.

Those engaged in cyberstalking often try to disrupt existing friendships either directly or by pretending to be the victim (such as through hacking) in order to send messages to a third party. This latter form of cyberstalking has two-dimensional victimization. The victim suffers the disruption to their normal social activities by the perpetrator. However, further victimization then occurs by the fact that the third party believes the victim is the aggressor rather than the perpetrator. This can lead to disrupted friendship or social groups, increasing the distress suffered by the victim.

Other forms of cyberstalking/cyberbullying can include *flaming*, a type of communication that includes offensive comments made to the victim. In recent years, a number of well-known women have been sent highly misogynous messages after speaking publicly about issues surrounding the status of women in society. This has included, for example, rape threats and threats of physical violence. It is easy to dismiss such matters as empty threats, perhaps because it was thought unlikely that the victim's location would be identifiable. People do feel fear of such messages, however, and the threats can be combined with information from social media to make their location specific, increasing the anxiety of a victim.

Cybertalking/cyberbullying can also take on the form of *outing* where personal details are released about a victim. This may include, for example, the name and address of an individual (which could compromise the individual's safety) or details about the individual's personal life. A particularly unpleasant form of outing is where their contact details are placed on adult sex sites, with a message that suggests that the victim, for example, is willing to engage in sexual activity with strangers (or the victim's children are). This not only potentially places the victims at risk physically but can be extremely traumatic for them, particularly where work colleagues or others may have seen the posts.

Revenge Pornography

Perhaps the latest form of Internet victimization that has come to public attention has been given the term *revenge pornography*. Typically, this behavior involves a couple who have (consensually) filmed themselves having sexual relations with each other. When the relationship breaks down, one party posts the footage online, usually accompanied by metadata that identifies the victim, allowing it to be discovered via Internet search engines.

Revenge pornography first entered the public consciousness when Hunter Moore created a website called Is Anyone Up in 2010. The site actively solicited revenge pornography, ensuring that details of the victim would be known. When victims contacted Moore, he either charged them a significant fee to (allegedly) take down the

material or posted their messages on the site, accompanied by sarcastic comments.

Moore was eventually prosecuted for arranging for computers to be hacked to steal intimate photographs. Since his prosecution, many similar sites have emerged with revenge pornography now a big business (attracting both subscribers and advertising). Many countries have not criminalized revenge pornography because the initial footage was recorded consensually. However, there is concern about the consequences for the victim. While some may not mind intimate partners seeing them naked, the same is not true of complete strangers seeing them. Once these images are posted neither partner has control over them and they can never be truly deleted, as they can be mirrored (posted on numerous websites), downloaded, or traded.

Many countries are now beginning to establish laws against revenge pornography. The laws usually address the nonconsensual distribution of a sexual photograph of another. Some countries' laws require an intention to cause distress, which is not always easy to prove, but at least it is recognition of the harm that ensues from this behavior.

The Internet has provided new opportunities for individuals to be victimized. Individuals' online behavior arguably assists with this victimization. Many individuals are prepared to bestow friendship status upon someone quicker online than they are off-line. Yet their feelings of betrayal, hurt, and anger are as powerful toward this online *friend* as they are for those off-line. The Internet is sometimes considered to have a distancing effect but that does not seem to be true when a person is victimized, with the effects being felt just as powerfully.

INTIMATE PARTNER VIOLENCE

Intimate partner violence refers to a specific form of domestic violence that refines the relationship status of the parties involved to include spouses and short-term and long-term relationships, both heterosexual and homosexual. Although the phrase *intimate partner violence* is often used interchangeably with *domestic violence*, the latter term includes additional types of relationships between the involved parties such as children, family members, or any member of a household (even roommates). Historically, this violence has included acts such as homicide, rape, robbery, and assault; however, the definition of intimate partner violence and the various acts encompassed therein have been refined and expanded over time. Broadly speaking, intimate partner violence can take the form of any of the aforementioned physical and sexual acts as well as nonphysical acts such as stalking and various psychologically based acts including emotional abuse and behaviors aimed at controlling a partner.

In the United States, intimate partner violence is an issue of importance to criminal justice agencies, public health officials, and practitioners alike. In the 1970s, sociologists and criminologists began to identify the issues of domestic violence and the more specific form, intimate partner violence. Despite its relative infancy as an area of academic inquiry and practical response, intimate partner violence is considered by some to be a behavioral phenomenon of temporal and spatial ubiquity: It is found in many places across many time periods in the world's and nation's history. This entry focuses on the prevalence and incidence of intimate partner violence in the United States.

Physical Violence

Physical acts of intimate partner violence can be grouped via their official classifications such as homicide, robbery, and assault or via their more commonly used descriptions such as slapping, hitting, and beating. Some surveys and measurement instruments classify physical violence, in terms of assaults and acts including this crime, separately from homicide. Even based on this slightly more restrictive definition of physical violence, its prevalence is considered quite high.

Approximately one in four women and nearly one in seven men in the United States have, at least once, experienced physical intimate partner violence in their lifetime. In terms of frequency, this equates to approximately 36 million women and 29 million men who have experienced physical violence at the hands of an intimate partner in their lifetime. Annual figures estimate that 3 million women and more than 2 million men have experienced severe physical violence within the past year. Despite those numbers, research has shown a gradual and steady decline in the occurrence of intimate partner violence in a two-decade period following the 1993 redesign of the National Crime Victimization Survey. Much of this decline can be attributed to the significant decline of female victimization. This decline is seen across all subtypes of victims whether they are examined on the basis of age, race and ethnicity, or marital status.

Sexual Violence

Sexual acts of intimate partner violence can be grouped via their official classifications such as rape, sexual assault, sexual coercion, unwanted sexual contact, and unwanted noncontact sexual experiences. Generally, the data that are used to describe sexual violence encompass criminal acts such as rape and sexual assault between intimate partners. Historically, women constitute the majority of victims of sexual intimate partner violence. Most victims (70% of females and 50% of males) experience their first instance of intimate partner violence before the age of 25 years.

In the United States, nearly 9% of women and approximately 1% of men have experienced rape by an intimate partner during their lifetime; nearly 1% of females have experienced the act within the past year. These figures rise dramatically when examining other forms of sexual violence by an intimate partner. Nearly 16% of women and 10% of men have experienced a sexual act of intimate partner violence other than rape. Estimates show that 2% of women and men have experienced these acts within the past year. Examining these acts by their frequency may better represent the scope of the problem. Over one's lifetime, it is estimated that 19 million women and 11 million men have experienced rape by an intimate

partner; 29 million women and 16 million men have experienced any other form of sexual intimate partner violence within the past year.

Stalking

Stalking differs greatly from the previously discussed acts of interpersonal violence. Stalking, instead, involves harassment or threats that instill fear in the victim. Tactics involved in stalking are not, by themselves, deviant or illegal. However, their unwanted and patterned use, along with their effects on the victims, makes them criminal. These acts may include any form of unwanted contact or communication, watching or following, spying, unwanted arrival at a victim's home, place of work, or school, and leaving potentially threatening items or messages for a victim to find.

Nearly one in six women in the United States has experienced stalking at some point in her life, a far greater proportion of the population than the one in 19 U.S. men who has experienced the same form of victimization. The likelihood of multiple victimizations is higher for women than men. Most victims of stalking experience the acts at the hands of just one perpetrator; however, some victims have reported multiple perpetrators. Female victims experience stalking by two perpetrators at nearly twice the rate of male victims. There is little difference in the prevalence of stalking victimization by race and ethnicity. The forms of stalking, however, are far from equal in terms of their experience. A majority of stalking victims report receiving unwanted phone calls, voice mails, hang-ups, or text messages. The next most common forms of stalking are being approached by a perpetrator unwantedly and being watched or followed.

Psychologically Based Acts

In addition to stalking, there are various other forms of nonphysical intimate partner violence that are used to intimidate, instill fear, or control the victims' behavior. These psychologically based acts constitute the most prevalent type of intimate partner violence. Nearly half of all women and men in the United States have experienced some psychologically based act of intimate partner violence. These acts may include emotional abuse in

the form of denigration such as insults, controlling access to money, restricting interaction with friends and family, making threats of harm to oneself or loved ones, and limiting mobility by restricting access to cars or other forms of transportation.

The most common act of this form of intimate partner violence involves tracking the victim's location and acts and behaviors while not at work or in the home. This is found for both female and male victims. There are gender differences, however. Female victims experience emotional abuse in the form of insults, humiliation, and other forms of patterned derogatory remarks at a higher rate than male victims. Intimate partner violence in the form of threats of harm, various controls of access, and restricting interaction with friends and family is experienced at a much lower rate by male victims than female victims. Female victims are also subject to control of reproductive or sexual health by an intimate partner. However, research shows that male victims experience these forms at similar or even higher rates than female victims.

Effects of Intimate Partner Violence

The effects of intimate partner violence are not acute nor are they limited by the extent of physical violence. Victims of intimate partner violence can experience changes in temperament and thought patterns due, in large part, to fear or post-traumatic stress disorder and physical symptoms and ailments as the result of severe and/or chronic abuse. Intimate partner violence has also been linked to health concerns and afflictions such as frequent headaches, chronic pain, difficulty sleeping, and poor mental health. Physical symptoms and effects have been found to be associated with particular genders. For example, the effects of intimate partner violence on women have long been documented to be more severe and long lasting and include ailments such as asthma, irritable bowel syndrome, and diabetes.

In addition to the medical resources needed for successful recovery following an incident of intimate partner violence, intimate partner victims need resources for—at least—temporary survival. These resources include shelter and housing, victim advocacy services to aid in the procurement of restraining orders and/or *pressing changes*, legal counsel, and gynecological and/or maternity

services. The most common services needed for both female and male victims of sexual intimate partner violence include the redress of fear, safety concerns, and symptoms of post-traumatic stress disorder. As a result, primary services for victims of intimate partner violence can be and are provided for acute treatment: physical health, mental health, and temporary safety and shelter.

The best response, however, may be prevention. Intimate partner violence has been found to first occur at a young age, leading to compounding and increasingly detrimental effects over time. Thus, the impact is neither acute nor short term. Proposed prevention efforts include programs such as those that educate communities and promote healthy, respectful relationships within the family on a continuing basis. To address patterns of intimate partner violence, or repeat victimization, which is quite common, appropriate services must be available. These services are overwhelmingly described as being most effective when they are coordinated: multiple agencies and groups working collaboratively.

These services may include health care, legal services, mental health treatment, housing services, and other resources that may be required to address the needs of the victim and/or those affected peripherally such as children and other members of the household. In addition, many strongly advocate for an enhanced criminal justice response to the perpetration of intimate partner violence to hold offenders accountable and to, as a result, engage, support, and perhaps even empower victims. Finally, much of the data that is available concerning intimate partner violence is through official criminal data instruments such as the National Incident-Based Reporting System and national-level surveys such as the National Intimate Partner and Sexual Violence Survey and the aforementioned National Crime Victimization Survey. Although these instruments provide valuable yearly estimates of incidence, prevalence, and, in some cases, individual characteristics of intimate partner violence, there is no national data system to monitor intimate partner violence specifically. Surveillance and evaluation systems may provide more immediate and useful information for law enforcement, service providers, and victims of intimate partner violence. These data could also aid stakeholders and policy makers in creating programming and legislative initiatives to support

victims of intimate partner violence and provide resources for the redress of its acts.

INTIMIDATION

The word *intimidation* has a wide range of meanings in social and biological sciences. In the *Oxford English Dictionary*, *intimidate* means to “frighten or overawe (someone), especially in

order to make them do what one wants.” It can be used as a verb (“The thought of a police officer watching Jim shoplift intimidated him”), an adverb (“The professor looked at students intimidatingly if she thought they were cheating”), or a noun (“Bullies are intimidators”). Intimidating behavior occurs across the animal kingdom. Social scientists have studied human intimidators’ words and gestures that frighten, scare, threaten, bully, and harass their victims. Biologists have studied intimidation in the form of survival mechanisms among predators and prey in food chains. Researchers studying intimidation in humans’ verbal and nonverbal communication have searched for definitive cues that distinguish intimidation from other similar behavior: bullying versus friendly playground pushing and shoving among youngsters; sexual harassment versus off-color humor and flirtatiousness in workplaces. Political stump rhetoric that seeks to influence voters’ opinions on school levies or roadway infrastructure reconstruction can be transformed into rhetorical intimidation with an inclusion of selected words and gestures that instigate fear in voters on sociopolitical issues, such as war refugees’ emigration to the United States. This entry reviews intimidation in the context of criminal psychology and culture.

Intimidation or Criminal Psychology

Polite communication can be dramatically altered by intimidating words and gestures, such as rude speech or threats of aggression. Kenneth Dodge’s theory of psychopathological conduct disorder among dysfunctional children incorporates the concept of intimidation. A conduct disorder is a sociopsychological pathology displayed when everyday external stimuli trigger exaggerated or aggressive outbursts. One such conduct disorder is antisocial personality disorder. According to the Mayo Clinic, risk factors for antisocial personality disorder include childhood abuse or neglect, childhood exposure to violent or chaotic family life, and a family history of antisocial personality disorder or mental illness. Symptoms of pathological conduct disorders evident in intimidators include purposeful chronic and deliberate threats that engender fear in others. Their behavior

reveals symptoms of mental abnormalities, which preclude victimizers' conscious ability to control their intimidating behavior. These chronic intimidators exhibit a criminal psychology.

Culture and Intimidation

American culture inculcates children with verbal and nonverbal cues unique to American society. Children acquire the meaning of gestures, such as waving goodbye or smiling hello. People socialized into American culture understand the difference between the meaning of a friendly wave goodbye and a threatening shaken fist. Schoolchildren can distinguish between verbal teasing or friendly touching among friends versus intimidating verbal harassment and bullies' aggressive shoving. Yet, words and gestures alone convey limited information. Social contexts (e.g., morning business meetings vs. post-work pub gatherings) and ways of speaking (e.g., loud voices infused with agitated hand and excited facial gestures at football games vs. quiet voices and solemn expressions at religious services) influence the meanings of verbal and nonverbal cues. John Gardiner's theory of communication known as *transaction analysis* posits that communication is a verbal and nonverbal transaction between message senders and receivers. Effective, meaningful communication requires that senders and receivers share a body of knowledge of verbal and nonverbal cues and of intended meanings of those cues. Speakers' words and gestures can have an intimidating or friendly effect on listeners, if senders and receivers share a common body of knowledge of verbal and nonverbal cues.

Cross-Cultural Intimidation

Cross-cultural communication research has learned that intimidation can occur as a misinterpretation of verbal and nonverbal cues between senders and receivers in diverse cultures or socioeconomic groups in the same culture. Cultural communication, in general, aligns on two scales: one scale denotes emotions, and the second denotes confrontation. Highly emotional and confrontational forms of conversation, customary ways of speaking in some cultures or subcultural groups, can be misinterpreted as aggression and

intimidation in different cultures and subcultures. Miscommunication between members of different socioeconomic groups can occur if these groups have contrasting styles of communication. Police may be called to investigate shoppers' allegations of coercive intimidation or physical threats by a panhandler's request for spare change as he extends an empty coffee cup toward shoppers.

Verbal and nonverbal behavior can be misinterpreted. For example, friendly teasing among school mates might be mistaken by a new student as bullying. The difference between jocular teasing and verbal harassment poses evidentiary challenges for attorneys, who defend or litigate against school districts that purportedly allow bullying behavior or gender harassment to continue unabated.

Legal Controversies

Social scientists' studying intimidation in sociolegal, sociopolitical, and sociocultural contexts have identified intimidation in numerous contexts: jury witness intimidation, hate crime, gender discrimination, gang intimidation, voter intimidation, sexual assault, bullying, hostile workplaces, sexual harassment, and terrorism. State legislatures have responded to intimidation with statutes that prohibit it and specify sanctions imposed on intimidators.

School Bullying

Unlike assault and discrimination, bullying is not illegal. Some states have tried to limit bullying by mandating school-based, anti-bullying policies. In 2002, New Jersey passed a law standardizing school districts' anti-bullying practices. That law combined harassment, intimidation, and bullying into a single operational standard and mandated policies governing school suspension. New Jersey's anti-bullying standards focus on acts motivated by a student's sociodemographic characteristics, such as race, gender, and sexual orientation, which cause him or her harm, or place him or her in immediate fear of harm, or demean him or her in such a way as to cause a substantial disruption of the orderly operation of a school. New Jersey's statute differs markedly from the Center for Disease Control and Prevention's definition of

bullying, which focuses on an imbalance of power between a bully or harasser and a victim.

Social Media and Witness Intimidation

Social media has revolutionized witness intimidation. Incidents of face-to-face intimidation purveyed by gossip have now been morphed into web-based intimidation and harassment by anonymous agents. Social networking platforms, including Facebook, Instagram, and Twitter, have promoted social interaction and social intimacies into a public forum. Web-based platforms have also been used to threaten witnesses in criminal cases, by displaying their home addresses and posting transcripts of their courtroom testimony.

Witness intimidation prior to criminal trials has become a public safety crisis. Witnesses who are intimidated often experience fear of being tracked down, threatened, beaten, or killed. State courts have responded to social media's role in community-wide witness intimidation with judicial and legislative reforms, including modification of social media platforms in ways that do not threaten free speech. Judges in Florida can withhold names of witnesses testifying against a defendant when his or her testimony poses a substantial risk to his or her safety. In Pennsylvania, judges can hold pretrial, private grand jury hearings, a practice that limits witnesses' vulnerability. In Maryland, amendments to the Maryland Rules of Evidence now allow a witness's statement into evidence without forcing witnesses to testify in open trial. That amendment prevents disclosure of his or her identity by testifying at trial.

Curbing Intimidation

Acts of intimidation disrupt social order. Bigotry on the basis of sex, gender, race, religion, and ethnicity is a form of intimidation that has continued to foster challenges to the social and moral order of the United States. Now, the concept of intimidation has become a prevalent topic of social science research and has emerged as a critical issue in law enforcement recognized by state and federal lawmakers. Elected officials and state and federal courts have acted to curb intimidation, in all its forms, such as gender harassment. Legislation has acted to mitigate web-based intimidation. A major

challenge ahead focuses on mitigating intimidation in cross-cultural and subcultural miscommunication. Systematically diminishing harm incited by intimidation can help future generations establish a recognizable social and moral order predicated on mutual respect and civility.

INTRAFAMILIAL CHILD MOLESTATION

Sexual offenses such as molestation (i.e., at its core, any sexual abuse of another person but could also include the pestering of someone in an aggressive or ongoing manner) that take place within the family can be quite disturbing and often evoke feelings of disgust. However, when it is acknowledged that one in four girls and one in five boys are sexually abused before the age of 18 years *and* that most perpetrators of sexual offenses are family members or people close to the family,

it should not stand out as rare. Family structures and relationships can be complicated, and sexual offending can take many forms within a family. The most researched offense is child sexual abuse in which an adult family member takes advantage of a minor child in the family for the purposes of sexual gratification. This may include fondling, simulated sexual intercourse, oral-genital sexual contact, digital penetration, and, in some cases, vaginal or anal intercourse. Other inappropriate sexual interactions such as grabbing buttocks or breasts (i.e., sexual battery), adults showing children pornographic material, or engaging in sexual acts with other adults in front of children are also forms of sexual offending. Generally, intrafamilial sexual offenses take place between individuals who have significant familial relationships to each other and whose relationships would generally prohibit them from marrying each other in most modern developed countries.

The term *incest* has historically been reserved for the act of intercourse taking place between family members, including instances between consenting adults. In circumstances in which individuals are not related by marriage, generally relationships lasting at least 2 years can then fall into the category of intrafamilial. For example, if an adolescent female was sexually victimized by her mother's live-in boyfriend who has resided with them for 2 years, it would be considered intrafamilial given the definition in the field. The variety of offenses that can take place between family members is almost as vast as the potential types of relatedness. The entry examines various types of intrafamilial sexual offending behaviors and their impact on the victims.

Offending Behavior

Approximately one third of intrafamilial offenders sexually abuse more than one child within the family. Additionally, a third of intrafamilial offenders admit to having both male and female victims. These data mimic wider research that indicates there is a great deal of gender crossover in the victimologies of child molesters. The majority of intrafamilial offenders have more than one type of contact offense against their victim, and a good number of them also engage in some sort of non-contact offense against their victim (e.g., indecent

exposure). The most common age range of the victim is 8–12 years. This is a school-age child who may spend more time unsupervised but who is still quite reliant on parents and family. Although a 12-year-old may be approaching pubescence, this age range is still very vulnerable. Alternatively, other research that focused specifically on father-daughter and stepfather-stepdaughter incest has indicated that the perpetrators were often absent from the victim's early childhood (3–6 years of age) and that the onset of abuse was near the time the girl entered puberty.

Some of the aforementioned behaviors may indicate that an offender is grooming a child for a planned sexual offense. Grooming occurs when a perpetrator has identified a potential victim and uses attention, bribery, or sexual desensitization to violate the child's boundaries and help shape the child's environment to facilitate compliance with an act of sexual abuse.

Researchers agree that abuse at the hands of an adult family member tends to happen more frequently and over a longer duration than offenses committed by nonfamily members. This can simply be explained by the regular exposure with a child who lives in the same household, as opposed to the nonfamily member who would have to make more effort to come into contact with the child.

Correlates or common attributes of incest offenders include the lack of a sexual partner, intimacy deficits, social isolation, marital discord, role-reversal (of child and nonoffending partner), impulsiveness, and feelings of low self-worth. Regarding role-reversal, when a father or stepfather offends against his daughter or stepdaughter, the victim has generally stepped into the role of *wife* in various aspects within the home (e.g., cooking, cleaning, child-rearing) and eventually as the sexual partner of the perpetrator. This replacement of a partner is also common when women offend against their own children.

Female Offenders

There is significantly less research on female offenders due to the fewer cases to study. Female offenders are not reported to law enforcement as often as male offenders, they are not formally charged as often as their male counterparts, and

when they are charged, they receive lighter sentences. These barriers make it difficult to obtain research on the female sexual offender.

However, researchers have found that women who offend against their own children were often victims themselves of severe emotional, physical, and sexual abuse in childhood. They tend to experience substance abuse disorders and are unable to form secure attachments, often entering into abusive adult relationships. They also present with more psychotic disorders and personality disorders than male offenders. For women who offend alone against their own children, they may be replacing the emotional closeness of an absent adult partner. For those women who have poor boundaries or less than optimal judgment stemming from childhood victimization or more current problems, emotional intimacy blurs with sexual intimacy. Women also inflict sexual abuse onto children as co-offenders or by offering up their children to another adult. The motives behind these types of offenses are rarely connected to an actual sexual interest in children and more often related to pleasing a boyfriend, being overly sexually preoccupied due to substance intoxication or being coerced into the action by the male partner.

Other Types of Intrafamilial Sexual Offenses

Individuals who can be victims of intrafamilial sexual offenses include parents, children, aunts and uncles, first cousins, grandparents, and grandchildren, as well as nieces, nephews, siblings, and the immediate family of a spouse. Although it has not always been illegal, spouses may and do offend against each other and would be considered in the category of intrafamilial sexual offending as well. Spousal rape is a unique part of intimate partner violence. One third to one half of battered women reported being sexually assaulted by their intimate partner at some time during the relationship. Men who sexually assault their spouses tend to have several characteristics in common including attitudes that support sexual offense-type behavior. They are deficient in their communication skills, lack emotional intimacy, and view the refusal of sex by their spouse as *intolerable*. As with most men who sexually

assault adult women, there is an underlying distorted thinking pattern of hostility toward women and sexual entitlement with these men.

The majority of spousal sexual assaults include physical and emotional abuse as well as other acts of violence (e.g., grabbing, slapping, kicking). Strangulation is another violent behavior used in over a third of spousal rapes, and some offenders used weapons to control their victims. Victims of spousal sexual assault report other incidences of sexual abuse within the relationship, being coerced into sexual activity, and their spouse having sex with them when they were unable to give consent. Most women who are sexually assaulted by their husbands reported that the perpetrator used violent sex to *prove his manhood*.

Impact of Abuse on the Family

Sexual abuse has many short-term (up to 2 years) and long-term effects on the child victims and can be amplified when the perpetrator is a trusted family member. Short-term effects on younger children can include regressive-type behaviors such as thumb sucking, bedwetting, or a decrease in verbal speech. They may also develop sleeping or eating difficulties and be unwilling to interact with others on a social level, including withdrawing at school. Sexual abuse victims also experience a diagnosable mental health condition such as mood and anxiety disorders following the abuse. Most common is anxiety related to thinking that someone will find out about the abuse or that the abuse will happen again. Depression, which is closely related to anxiety, most frequently follows abuse incidents, particularly if the abuse is not reported. In most cases, the child will isolate and experience sadness, coupled with a heavy sense of worthlessness.

Generally, long-term effects for child sexual abuse victims are vast and depend on the resilience of the victim as well as the success of therapy focusing on the abuse. Behavioral consequences can include involvement in unhealthy adult relationships, risky sexual behavior, and self-destructive behaviors such as substance abuse and eating disorders. Prostitution and runaway-type behaviors are also particularly common with incest victims. The early sexualization of a prepubescent child can have severe effects on the

cognitive and emotional development of the child's sexuality. Sexually abused children may blur the lines between attention, love, and sex. This can manifest into dysfunctional relationships as they age and forever change their worldview on sexuality. Feelings of anger and betrayal are particularly strong emotions experienced by individuals who have been abused by family members.

If the abuse did not involve force or violence, research indicates that victims may not feel traumatized or victimized at the time of the offense. The feelings of trauma may come later after they learn that the sexual activity was *wrong*. This can exacerbate feelings of confusion, especially when a trusted relative is the offender.

Myth and Risk

The most common myth regarding intrafamilial sexual offending is that it *stays in the family*. A significant amount of research since the mid-1990s indicates that many intrafamilial offenders have admitted to previous nonincest sexual offenses. Additionally, nonincest offenders have also admitted to past offenses within their own families.

However, regardless of the age or gender of the victim, offenders who victimize family members have lower numbers of victims among all sexual offenders and are less likely to be arrested for new sexual offenses after the initial conviction. The Static-99R, one of the most widely used risk assessment tools for predicting future sexual recidivism based on static risk factors, includes an item regarding relation of the victim to the offender. Research indicates that individuals who are willing to go outside of the family to seek and victimize individuals are at higher risk of future offending. The levels of antisociality and pedophilic disorder (as measured in phallometric lab settings) among intrafamilial offenders are quite low when compared to nonincest child molesters. Once an intrafamilial offender has been detected and there is an intervention (e.g., therapy, incarceration, monitoring), the offender is at very low risk to commit another sexual offense in the future.

Overall, intrafamilial types of offenses are less likely to occur between more closely related family members, and the victim is more likely to be female with a male perpetrator. Offenders are less driven by a pervasive sexual interest in prepubescent

children and are more likely to sexually victimize children who are developing or have developed secondary sex characteristics. In the general population (not considering incest situations), it is not atypical for an adult male to be sexually attracted to an adolescent, postpubescent female. Although intrafamilial offenders share several common dynamic risk factors with other sexual offenders (e.g., lack of a satisfying sexual relationship with an appropriate partner, negative emotionality, lack of intimacy), with the provision of treatment interventions, research demonstrates that intrafamilial offenders often have success in remaining offense free in the community. Indeed, there are anecdotal accounts of related offenders and victims being able to move on and form healthy, appropriate relationships after the abuse, generally with the assistance of consistent therapy. It is most appropriate for such reunification when the victim reaches adulthood and can make decisions for himself or herself that are not influenced by the desires of other family members, guilt, or impulsiveness.

INTRAFAMILIAL CHILD MOLESTATION, THEORIES OF

Intrafamilial child molestation refers to child sexual abuse involving contact between a child and another family member, often within the same household, and includes molestation by stepparents, common law parents, live-in parent figures, and other blood relatives not in the same

household. Several models and theories have been offered to explain the dynamics involved in intrafamilial child sexual abuse. Several of these are discussed in this entry, after discussing victims' disclosure of the molestation and offender profiles. The entry concludes by discussing the association between intrafamilial child molestation and victims' adult functioning.

Disclosure of Molestation

Surveys demonstrate that only one third of child molestation survivors disclose their abuse during childhood, and 60% delay disclosing for 5 years or more after the first child molestation episode. Many survivors may even wait upward of 20 years before disclosing their abuse, while 20% of survivors never do disclose. Disclosure is a relational process, which varies with interactions and evolves over an extended period of time, especially since intrafamilial child sexual abuse tends to involve multiple episodes over an extended period of time. As peer relationships are particularly important during adolescence, friends may be particularly important recipients of disclosure information.

When surveyed, it is not uncommon for adults who were child victims of incest to disclose their abuse to psychologists or therapists; however, it is rare for them to disclose to their family of origin, especially if the perpetrator remains among the nuclear family. When adults do disclose their abuse, the disclosure is purposeful and direct. Those victims who have faint or confusing memories, however, rarely disclose as adults.

Intrafamilial offenders, unlike extrafamilial offenders, may isolate the victim from other family members (e.g., nonabusive parent, siblings, outside relationships), by developing an exclusive relationship with the child. In the case of parent-child incest abuse, the child victim is sometimes promoted in place of the other parent. The offender may groom the child for sexualized behavior by giving him or her gifts, extra privileges, and attention. Children often become eager to please their abusers, without understanding their abusers' true intentions.

Upon suspicion or knowledge of intrafamilial molestation, concordant maternal belief and protective action by the mother is more likely when the mother has reached adulthood prior to

childbirth, and the mother is not in a sexual relationship with the offender. Mothers who do not have prior knowledge of their child's sexual abuse are more willing to believe their child's disclosure. However, children demonstrating sexualized behaviors are deemed less reliable by the nonoffending parent and nuclear family. These sexualized acts can taint the child victim's unconscious cry for help and adult intervention, even though the child victim may not psychologically understand his or her feelings or physically understand his or her body's language for several years.

Offender Profiles

The majority of female and male child sexual abuse offenders are male, but there is a paucity of published studies documenting females as primary or passive sexual abuse offenders in female and male child sexual abuse cases. Nonetheless, documented cases of female offenders and male sexual abuse victims are increasing. It is worthwhile to note that 3–17% of adult men have been traumatized by child sexual abuse.

When asked, about 33% of incarcerated offenders, surveyed for intrafamilial molestation, said that they had experienced or were exposed to sexual abuse as a child. Approximately one half of the victims' mothers had also experienced or were exposed to sexual abuse as a child. Based on previous studies, if the offender is the biological father of the victim, both parents are equally likely to have experienced sexual abuse during childhood. When the offender is a stepfather or live-in partner, the victim's mother is more likely to have had these experiences. In cases in which the offender is a noncustodial father, he is more likely to come from a sexually abusive family.

Intrafamilial offenders and extrafamilial offenders differ in many ways. Intrafamilial offenders are often more intelligent, yet they usually obtain lower educational milestones, than extrafamilial offenders. Intrafamilial offenders come from histories of maltreatment and poor parent-child attachments; some general violence and little nurturing are common in these households. Despite difficult childhoods, intrafamilial offenders have slightly fewer antisocial tendencies compared to extrafamilial offenders. Intrafamilial offenders also have fewer atypical sexual interests, social

problems, and personality disorders than extrafamilial offenders. Intrafamilial offenders have less emotional congruence with children than do extrafamilial offenders.

Emotional congruence with children refers to exaggerated cognitive and emotional need for childhood and children. For child molestation offenders, their emotional attachment and dependency needs are likely met by interactions with children. There is a lack of research, exploring offense-related psychological risks associated with such emotional congruence with children. Therefore, the following three factors should be considered for exploratory research: If sex offenders are blocked from satisfying intimate relationships, they may feel the need to reach out to children, as a less threatening and equally desirable partner. Some sexual deviants, beginning in their adolescent years, are attracted to children and prefer children as intimate partners. Other offenders may have a preoccupation with sex or poor sexual self-regulation, which may co-occur with emotional congruence with children.

Sibling sexual abuse offenders are usually not much older than the child victim. Adolescent sibling intrafamilial offenders are typically from more dysfunctional families than are adolescents who have sexually offended against unrelated children, peers, or adults. Around the mid-1990s, 12–70% of the intimate partner violence cases co-occurred with child sexual abuse and other maltreatment. It appeared that children were at greater risk for child sexual molestation when exposed to intimate partner violence. In these dysfunctional families, the mother's role is often reversed with one or more of the female children.

Models of Incest Abuse

The following models present different scenarios by which an offender may initiate intrafamilial sexual abuse. These factors can interact and work in parallel to result in incest abuse. The most evidence-backed models are briefly reviewed.

Feminist Approaches

The feminist approach is based on the traditional masculine notion that views girls and young women as property. In this context, the father figure has a *right* to all properties, including the

bodies of young girls living in the household. Family dynamics are not emphasized in this approach.

Multifactorial Approach

The multifactorial approach considers five factors: sexual needs, attractive children, opportunity, disinhibition, and sexual acts. Whether in print or person, attractive children awaken a child sexual predator's desire. It is only when the opportunity exists that these desires can be fulfilled. In this model, each intrafamilial sexual act serves to fuel the perpetrator's temporary loss of inhibition, facilitating his offending over time and satisfying his sexual needs at the expense of the health and safety of others.

Family Systems Model

The family systems model de-emphasizes social and cultural influences on intrafamilial sexual relationships, whereby instead, incestuous acts are viewed as symptoms of pathological family dynamics. For instance, the mother–daughter roles are sometimes reversed, especially with older prepubescent girls. The family is also likely to be isolated socially, and sometimes physically, from other families and communities.

Ecological Model

Four factors are emphasized in the causation of intrafamilial child molestation in the ecological model. First, families described in this model maintain a general level of violence in the home, while surrounding neighborhoods condone violence as well. Second, low socioeconomics are the norm for the area, which serves as a vulnerability for abuse. Third, socially, the women and children are viewed as inferior to male household members. The fathers are likely to be violent toward their wives and possessive of their children, leaving the maternal figure feeling helpless about the familial situation. Finally, daughters are left in a wake of fear, dependency, and naivete to these dysfunctional family dynamics, which leave them vulnerable to sexual exploitation.

Explanatory Theories of Incest Abuse

The pathways to intrafamilial sexual abuse are lined with family dysfunction, sexual deviance (i.e., abnormal, illegal, and potentially harmful

patterns of sexual interest and behavior), and offending opportunity. The following working psychological and sociological theories of incest reintroduce various aspects of the aforementioned models and interconnecting elements, which enable the repetitive cycle of child abuse.

Dysfunctional families involved in intrafamilial sexual relationships are likely to view sexually deviant behavior in a nonpathological light. For instance, sibling sexual behavior may be viewed as a safe or controlled way to prepare young girls for adulthood or an acceptable way for males to be sexually uninhibited. Invariably, if such psychological patterns are uninterrupted, they can have a damaging influence on the siblings' own adult sexual relationships, as sibling intimate relationships have become the sexual norm.

In the case of father–daughter incest abuse, as parental relationships are broken down, the mother becomes emotionally and sexually unavailable, at which time, a daughter may be put into the spousal role. Indeed, research has shown that approximately 86% of intrafamilial offenders are biological or stepfathers. Self-report studies examining women's sexual behaviors have noted a continued life of high-risk sexual behaviors after the first intrafamilial molestation experience. Without further studies and elaboration of experiences from the victims, their perceptions of healthy sexual relations will remain unknown.

From a sociological perspective, intrafamilial sexual behaviors are likely to occur when kinship cues (i.e., differentiating a relative from a nonrelative) are questionable or absent. These cues may include father's absences around or during time of conception, suspicion of the mother's infidelity, or perceived nonresemblance of the child's physical or personality traits. As a result, some fathers may engage in intrafamilial sexual abuse with little inhibition because they do not believe consciously or otherwise that the child is genetically related. These weak kinship cues would be expected to occur most frequently in fathers to create a dysfunctional family unit conducive to abuse.

Association Between Sexual Molestation and Adult Functioning

The preceding theories help to provide conceptual frameworks for associating intrafamilial sexual

abuse and sexual functioning. These frameworks function as guides for forensic interviewers and therapists to better understand a child's responses and behaviors. If children are vulnerable or distressed, they are supposed to be able to seek protection and care from their parents or caregivers. But in the context of father–daughter incest abuse, the mother may have become completely and emotionally unavailable to everyone. And when availability and responsiveness to the child is not available or does not exist, the child rethinks his or her importance or self-worth. So when an emotionally attached figure is responsible for perpetrating sexual abuse, the child is faced with the desire to be near a perpetrator for safety and security, while debating a decision about whether or not to flee from the incestuous demands. Naturally, children are incapable of organizing and responding to these situations from an adult perspective. Neither are resources always available to help these children make disclosures nor do children always feel comfortable disclosing their family dynamics. As a result, victimized children often recognize their boundaries as acceptable behaviors within the nuclear family and manage to function accordingly, to survive within their family.

Children develop internal working models to endure the intrafamilial maltreatment. These models may be representative of the child, others, or relationships. The models are shaped as a result of early attachment experiences and influence later adult relationship functioning. Information and data are not readily available, regarding the mental and physical health of victims of intrafamilial molestation. Extrapolating from the previous models, theories, and limited self-report studies, it is suggested that intrafamilial child sexual abuse may result in working models that evoke passive submission to risky sexual demands and limited sexual or intimacy boundaries.

INTRAFAMILIAL CHILD MOLESTATION, TYPOLOGIES OF

Intrafamilial child molestation is a form of sexual abuse that is perpetrated by someone considered *family*. Specifically, a family member, such as a

parent or sibling, involves or exposes children to sexual acts and behaviors by taking advantage of the child's trust and vulnerability. Research has shown that family members as perpetrators, immediate or part of the extended family, account for more than half of all sexually abused children. Children who are sexually abused, in turn, are more likely to develop significant psychological concerns including depression, anxiety, risky sexual behaviors, post-traumatic stress, difficulty forming stable intimate relationships, and suicidal ideation. Even more problematic, children who are sexually abused by family members are more likely to blame themselves for the abuse than children who are abused by extrafamilial (i.e., unrelated) perpetrators. These children tend to develop more symptoms of guilt, shame, and self-doubt and are less likely to report the abuse.

Although estimates vary, research has demonstrated that approximately 93% of all sexual offenders have displayed insecure attachment, defined as the bond between child and their primary caregiver, during childhood. These problems in attachment may have influenced coping, lack of empathy, and contributed to issues with intimacy with adults. Compared to nonoffenders, intrafamilial sexual offenders are more likely to have been exposed to, or victims of, sexual and physical abuse and other types of abnormal or atypical sexual experiences (e.g., child pornography) during childhood, including intrafamilial sexual abuse. These experiences during adolescence lead to mistrust of adults and the development of error in thinking about relationships (known as *cognitive distortions*), especially those with children. The offenders inevitably carry these distortions and experiences into their adult relationships, thus creating a generation-to-generation pattern of abuse.

Importantly, understanding the typologies of intrafamilial child molestation can lead to education and prevention of child sexual abuse. This entry reviews some of the common context and typologies of intrafamilial child sexual abusers.

Context of Intrafamilial Sexual Abuse

Intrafamilial child molestation, or incest abuse, is most often reported in the parent–child relationship, specifically the relationship between the

daughter and father. As it is far more likely that adult males will sexually abuse females to whom they are not biologically related, for this reason, adolescent girls are often more abused by their stepfathers than by their own fathers. It is also reported from survey research that grandfathers and uncles are likely to abuse as well. Although boys are less likely to be the victims of intrafamilial sexual abuse, when such abuse does occur, they are more likely to be both physically as well as sexually abused. In addition, most reports of intrafamilial sexual abuse come from lower socioeconomic status families; lower socioeconomic status typically correlates with higher levels of stress, which, as noted earlier, has been identified to be a contributing factor to regressed offenders' motivation for sexual abuse.

Parent-child incest is perhaps the most damaging to the victim because a parent's role as a caregiver is compromised. As the parent uses the child to fulfill their sexual needs, the child's perception of that role will become distorted, causing intense psychological distress. The child is dependent on his or her parent, thus allowing easy accessibility to the molester. The molestation may occur frequently over a long period of time and go unreported. Children who suffer from sexual abuse express it through their behaviors. For example, girls who are sexually abused often run away from home, attempt suicide, use drugs or alcohol, and sometimes become prostitutes. Some early psychiatric case studies of female prostitutes revealed a long history of early molestation and childhood rape by both family and nonfamily member individuals.

Often unreported, sibling sexual abuse may occur more than parent-child sexual abuse. It is harder to establish who the victim and offender are in sibling sexual abuse relationships where the ages of the children are similar. In parent-child sexual abuse cases, the offender breaks a generational boundary, but this is not the case with sibling intrafamilial molestation. In these types of cases, the offender may be modeling the parent abusing the child, thus identifying multiple sexual offenders. It becomes difficult to distinguish between parent-child sexual abuse and sibling sexual abuse when a parent inflicting the same or greater damage masks the damage inflicted by a sibling.

Sibling sexual abuse impacts the victim's self-esteem and overall well-being. A strong positive correlation exists between having positive sibling interactions and healthy romantic adult relationships, as well as positive self-esteem. Siblings often spend more time together and use each other as a buffer during times of parental conflict. For example, if sexual abuse is going on between a parent and a child, siblings seek out one another for comfort and understanding.

Many victims report poor adult relationships with their siblings when sibling relationships are compromised by sexual abuse and molestation during childhood. Some even expressed feeling like their siblings are distant relatives. This is unfortunate because sibling relationships can outlast the parent-child relationship as well as some friendships and marriages and are among the most beneficial adult relationships one can enjoy.

Intrafamilial Subtypes

Child sexual abuse offenders are often categorized into two major subtypes based on their motivations and characteristics: fixated and regressed. Regressed offenders tend to have *normal* sexual relationships and interests and are not typically sexually interested in children, while fixated offenders voice a preference for, and identify with, children. It has been argued in the literature that regressed individuals commit sexual offenses when they are experiencing stress and abuse children as a coping mechanism. For this reason, regressed offenders abuse children who are accessible to them such as family members or children of their support system. Unlike fixated offenders, however, they do not typically plan and go out of their way to commit these crimes. Instead, their behavior is impulsive, taking advantage of opportunity and situation. These abusers most typically victimize female adolescents. They are unlikely to have male victims or to display pedophilia, which is characterized as a fixation and sexual preference for children, often seen in extrafamilial child abusers. Moreover, those of the regressed typology tend to be less psychopathic or to exhibit violence toward their victims, in part given that they have usually spent a significant amount of time with the child before committing these acts. They also tend to have fewer victims and a lower rate of recidivism.

Subtypes of incest child offenders can be further differentiated by degree of aggression, underlying motivation of offender, presence of antisocial behaviors, and sexual versus nonsexual nature of assault and degree of control.

Sexually Preoccupied

The first subtype of incest offenders is the sexually preoccupied. These offenders demonstrate compulsive sexual behaviors that resemble an addictive disorder. That is, they may engage in these behaviors despite psychological or physical consequences, preoccupation with the behavior, and control of the behavior. These offenders often exhibit impulse control difficulties and have trouble suppressing urges and impulses. Incest offenders of the sexually preoccupied subtype may choose to molest children who are in the home due to accessibility and proximity. Incestuous fathers of the sexually preoccupied subtype demonstrate clear and conscious sexual interests in their daughters, often from an early age.

Adolescent Regressive

Offenders of the adolescent regressive subtype are fixated offenders who begin their preoccupation with children during adolescence. These offenders are typically emotionally immature, do not have healthy age-appropriate sexual relationships, and are preoccupied with children. Moreover, incestuous fathers have demonstrated conscious sexual interest in their daughters that only emerged following the daughters' onset of puberty. Adolescent regressive offenders may go to great lengths to establish relationships with children through excessive grooming or premeditation. Moreover, they may also dedicate their lives to be surrounded by children through their occupation or recreational time or hobbies (e.g., volunteering at church). These offenders may also target young males and are at increased risk of reoffending.

Instrumental Sexual Gratifiers

Instrumental sexual gratifiers are distinguished from the other subtypes because of their motivation. Unlike sexually preoccupied offenders who

have addictive patterns and poor impulse control, these offenders may use children for sexual gratification to complete fantasies about other partners. Specifically, for incestuous fathers, they did not experience sexual arousal for their daughters but rather used their daughters to fulfill their fantasies. These offenders often experience feelings of remorse and guilt for their actions, and their abusive activity tends to be less frequent than other typologies.

Emotionally Dependent

The fourth subtype is emotionally dependent offenders. These individuals are often lonely and depressed. These offenders romanticize the quality of relationship with the child victim and use the abuse to fulfill their needs for intimacy, closeness, and comfort. Therefore, the nature of the abuse is not specifically for sexual arousal but rather to elicit a significant bond with the child.

Angry Retaliators

Offenders of this subtype typically sexually abuse the child in response to anger toward their wife or the mother of the child for neglect, presumed or actual infidelity, and abandonment rather than for sexual arousal. These offenders may demonstrate long-standing problems with hostility and anger, low competence, and impulsive behaviors. They may also demonstrate antisocial and aggressive behaviors.

INVESTIGATIVE PSYCHOLOGY

Investigative psychology is a problem-solving psychology set up to deal with real-world crimes and other issues, beyond the abstractions of university laboratories. Investigative psychologists collect, assess, interpret, and organize the information available from an investigation. It is an emerging area of criminal psychology that utilizes psychology to bring together various data relevant to investigations to improve information on which an investigation is based, inferences related to that information (growing out of *offender profiling*), and the psychology of investigative decision-making. The findings, in turn, influence decisions that can be effectively supported. This field of psychology originates in studies of criminal activity, especially serious crimes, and has been utilized in a wide range of situations from examining the location of the improvised explosive devices in Iraq, identifying unqualified individuals attempting to gain welfare benefits, examining behavior in emergencies identifying the sources of anonymous offensive letters, to controlling crowds. This entry provides an account of the origins of investigative psychology and describes the frameworks drawn on to make inferences about an unknown offender or criminal group or network from how, where, and when crimes are committed. It also explores the ways that investigative approaches are changing as a result of input from investigative psychology.

Origins of Investigative Psychology

The idea that modern, scientific psychology can be of value to those investigating crimes has a long

history. One of the founders of modern psychology, Hugo Munsterberg, wrote *On the Witness Stand* in 1908 about psychology and crime over a century ago and Sigmund Freud gave advice to judges about distortions in memory. But the idea that psychologists can help solve crimes came into popular culture through fiction when Thomas Harris's book *The Silence of the Lambs* (1988) became a successful major film in the early 1990s. From that point forward, there has been an enormous amount of speculative writing that implies a clever psychologist can get into the mind of a violent criminal to solve crimes that flummox detectives. This has confused the reality of psychological contributions to investigations as these fictional accounts owe far more to the notion of fictional detectives such as Sherlock Holmes and many other subsequent fictional detectives than to any real scientific activity.

The real-life origins of current investigative psychology are usually linked to David Canter's contributions in 1986 to a major investigation in London related to a series of rapes and murders. Canter worked from simple principles drawn from social and environmental psychology that assisted the police to narrow down the range of possible suspects they had identified. However, many other researchers had been exploring interview procedures and the detection of deception prior to this as well as other areas of psychology relevant to the work of detectives. Consequently, in 1991, these various areas were brought together under the umbrella term *investigative psychology*.

Beyond Offender Profiling

Examples of making inferences about an offender on the basis of the actions related to a crime go back at least to biblical accounts and have always been present in law enforcement. However, the development of a formal framework that allows empirical testing of the validity of these inferences requires the elaboration of the inferences as a search for the relationships between the actions in a crime and the characteristics of the offender, often referred to as the $A \rightarrow C$ equation, or *profiling equation*. Solving this equation requires an identification of the salient actions in a crime, which can include time, date, and location, as well

as a clear definition and measurement of these. It also demands a focus on those features of the offender that are of utility to the investigation. Many studies have therefore been carried out to identify the co-occurrence of criminal actions within a subset of criminal activity. These studies have now covered the full gamut of crimes, including arson, burglary, hostage taking, murder (serial and single), rape, and terrorism. It is important to note that contrary to crime fiction, it is rare to find simple one-to-one relationships between actions and characteristics. The situation in which the crime occurs will have an influence on what the perpetrator does. Furthermore, offenders may learn from previous criminal experience and change their actions accordingly.

In general, a 4-fold framework has been established that covers, *mutatis mutandis*, all crime types explored so far. These have been linked to dominant narratives that underlie criminal actions, providing a theoretical basis for the inference process. These narratives are *professional*, *adventure*, *victim*, and *tragedy*. The emotional components of the criminal's experiences have also been correlated with these dominant narratives. Further, some crimes are more likely to be associated with one narrative than another; for example, many burglaries by young offenders are characterized as *adventure*, whereas many homicides are typically expressed as *tragedies* by their perpetrators.

The narrative framework allows the development and testing of hypotheses about the relationships between actions and characteristics. Although this research is in its early stages, results are emerging that provide the possibility of taking account of both the contingencies that influence an offender's actions and the likely development of those actions over criminal careers.

Geographical Offender Profiling

One area that has proven particularly susceptible to empirical scientific study has been the examination of the associations between where a crime is committed and where an offender is likely to be based. This is often referred to as *geographical offender profiling* and is of particular relevance to perpetrators who commit a number of crimes, often referred to as *serial* offenders. Although

many people are aware of the existence of people who murder a number of strangers over a period of time (i.e., serial killers), most perpetrators of crime commit more than one crime. Many burglars, for example, commit hundreds of burglaries. Geographical offender profiling is a special aspect of the aforementioned profiling equation. In this case, the actions are the crime locations and the characteristics are, typically, where the offender lives at the time of the offending. Studies of geographical offender profiling are revealing a considerable amount about the propensities of criminals as well as feeding directly into police investigations. The success of this research is due to the increasing availability of police geographical information systems in which the data are more precise than details of what actually happens in a crime. However, police geographical data are still far from wholly accurate, making many approximations necessary.

In general, two aspects of an offender's geographical activity have been identified. One is *propinquity*, which dictates that as the distance from the offender's home increases so the likelihood of a crime occurring decreases. This is known as a *decay function* because the reduction in the probability that a crime will be committed is more rapid the farther the crime location is from the home. However, this decay pattern is only found when examined across a number of different offenders, known as the *aggregate level*. It is rare to find that any one serial offender decreases the frequency of crimes at increasing distances from home.

The second is the *morphology* of the crime locations. In a large number of cases where offenders commit two or more crimes, and where the opportunities for crimes are evenly distributed around the home, the base of the criminal tends to be within the area circumscribed by those crimes. A simple way of modeling this is on a map, taking the two crimes farthest from each other and drawing a line connecting them that serves as the diameter of a circle. The hypothesis, often supported, is that the home will be within this notional circle. This is not to claim offenders think in terms of a circle of operation but rather to demonstrate a simple process for defining an area of criminality.

These two aspects of crime geography—*propinquity* and *morphology*—have been

combined into decision support systems, such as one called *Dragnet*, to carry out analyses on crime series as guidance to investigators. This contributes to the third component of investigative psychology mentioned in the opening paragraph—the psychology of investigative decision-making and how those decisions can be effectively supported. Rather than just generating interesting findings, investigative psychologists take the further step of converting those findings into processes and systems that can be directly used as part of a live investigation.

Linking Crimes to a Common Offender

All inference processes benefit from having information about more than one crime committed by the same perpetrator. The linking of crimes to the same person also assists law enforcement activities and obtaining a conviction in court. Therefore, a growing area of investigative psychology is exploring the possibility of linking crimes in the absence of forensic evidence, such as DNA, fibers, or witness descriptions.

In general, the proximity of crimes has been found to be the best predictor of crimes being linked. This follows from the propinquity principle because if crimes are close to the home they should be close to each other. This works well for rare, serious crimes, such as serial stranger rape and murder, but is less effective in areas that have a high density of frequent crimes such as burglary. Other markers, notably the similarity of actions in a crime, are therefore being investigated.

Effective Investigative Information

Without the initial stage of obtaining information about the crime being effective, no further aspects of finding culprits or proving their guilt are possible. Therefore, investigative psychologists contribute to the collection, assessment, and organization of the information available to an investigation. This includes improving the interview process, detecting deception, and considering such matters as false accusations and false confessions.

There have been great strides in recent years in understanding the investigative interview process. This has grown out of studies of memory and its

essentially constructive process as well as a more thorough understanding of the interpersonal transactions that are the essence of one person asking another questions. From these studies, an awareness of how malleable human memory is and the possibilities for genuine, inadvertent distortions have been revealed. These understandings have given rise to proposals for psychologically influenced interview procedures, notably the *cognitive interview* and the UK police forces Prepare, Engage, Account Clarification, Closure, Evaluation interview protocol. However, although these have strong theoretical roots, there are many challenges to carrying out these processes in practice.

The other area of information retrieval that has been extensively studied is eyewitness (and to a lesser extent *earwitness*) identification. The results of these studies challenge many popular assumptions about the ability of people to recognize a culprit after a crime has been committed. For example, the confidence eyewitnesses exhibit about their memory and/or identification of a culprit does not represent a simple relationship to the accuracy of that identification. Furthermore, a number of studies have shown that people can be led to genuinely think they remember something that has not happened. This investigative psychology research has helped cast doubt on many aspects of law enforcement procedures. The importance of this has been demonstrated in major revisions of many guilty verdicts that have become possible through developments in DNA identification. A high proportion of people convicted because of eyewitness testimony have been eventually found not guilty.

Supporting Effective Investigative Decision-Making

The mission of investigative psychology to contribute to law enforcement processes raises the requirement for psychological research results to be fashioned into decision support systems. As already mentioned, *Dragnet* and similar geographical profiling systems, while primarily research tools, are an example of a growing number of processes and computer-based systems developed to aid law enforcement. However, for these to be effective, an understanding of investigative decision-making

processes is necessary. Therefore, an increasing number of studies are exploring police decision-making.

Many of the studies focusing on the work of investigators draw on cognitive psychology, especially the study of decision heuristics. These have found, for example, that the *confirmation bias* is not uncommon in police investigations. This is the process of seeking information to support what is already believed to be the case rather than material that may disprove it. It has also become apparent that in those jurisdictions where police sometimes violate human rights, training in investigative psychology can provide an alternative, much more humane set of strategies and tactics for carrying out law enforcement. One powerful example is the demonstration that torture is of little value in obtaining useful information. Carefully prepared interviews built on developing relationships with suspects, victims, and witnesses are much more fruitful.

Investigative Psychology as a Coherent System

The three interrelated areas of information retrieval, inference, and decision support form a coherent investigative psychology system. Poor information cannot be used for effective inferences. Those inferences are no use if not formulated in a way in which investigators can act. Taken together, these open up a psychological approach to the consideration of criminality. Thinking of criminals as ordinary people doing illegal things provides a very different perspective from past dominant clinical psychology viewpoints that understood criminals to be odd, disturbed, or mentally ill. This was behind the Federal Bureau of Investigation claim that profiling was only relevant to *motiveless* crimes. In contrast, investigative psychology has been applied to common crimes like burglary and fraud not just the bizarre and extreme crimes. It is applicable to a wide range of investigations, far beyond crime, that is broadening all the time.

ISOLATION IN PRISONS

Although research is inconclusive, reports suggest that approximately 80,000–100,000 individuals are housed in isolation at any given time in the United States for 22–24 hr a day. Although this correctional measure is commonly reserved for inmates deemed the *worst of the worst*, findings reveal that inmates who are male, economically disadvantaged, and racial or ethnic minorities are disproportionately placed in solitary confinement. Further, it is necessary to acknowledge the harmful impact that segregation has on youth who are still developing physically, cognitively, and socially. Of particular concern is the fact that over a century of research indicates that the conditions of confinement exacerbate psychiatric disorders among inmates. Thus, given the exceptional risk associated with its use for this vulnerable prison population, this entry focuses on the isolation of inmates with preexisting mental illnesses, while also offering an overview of the practice of isolation and exploring its effects on mental health.

Isolation: An Overview

Although media coverage of the psychological harm stemming from solitary confinement in prisons has raised the public's awareness of this practice, its use can be traced to the very beginning of institutional corrections in the United States. Designed to promote obedience, order, and penitence, the early

19th-century Philadelphia and Auburn models entailed the use of solitary confinement. At Eastern State Penitentiary in Philadelphia, PA, which was completed in 1836, inmates were housed in single-cell isolation with only a Bible and handicrafts to occupy their time. In the penitentiary in Auburn, NY, which was completed in 1823, inmates performed congregate labor in silence and returned to solitary cells at night. While the guiding philosophy of the nation's first prisons seemed promising, housing offenders in isolation eventually garnered international criticism. The notably rapid deterioration of inmates' mental health, including those who had not previously exhibited symptoms of a psychiatric disorder, led to the dramatic decline in the use of segregation. As the *get tough* response to criminal offending gained traction in the 1980s and incarceration rates soared, correctional administrators once again turned to the use of solitary confinement as a means to manage burgeoning prison populations and contain and control those seemingly incapable of conforming to institutional rules of conduct and behavioral expectations. To accommodate the need for securing the *worst of the worst*, the nation witnessed the rise of the supermaximum security prison. More commonly referred to as the *super-max*, this new facility was designed to impose absolute solitude on individuals deemed a serious and chronic threat to the safety and order within traditional security level prisons.

Depending on the jurisdiction, isolation housing areas within prisons are referred to by a range of terms including *secure housing unit* and *intensive control unit*. While the degree to which solitude is exacted and the conditions in which inmates are confined vary among facilities, solitary confinement commonly entails placing an inmate in a single cell ranging on average 8 × 10 ft in size. Although the lights within the isolation pod may be dimmed during nighttime hours, they nevertheless remain on in order to facilitate monitoring of the segregated inmate's well-being and activities. Depending on the inmate's behavior, he or she may receive 1 hr for a shower and 1 hr of exercise time each day. The exercise cell is generally the size of the isolation pod and enclosed by barbed wire or concrete walls. As such, opportunities for any meaningful physical activity or exposure to natural sunlight and fresh air may be significantly limited. Mechanical restraints are utilized when moving inmates or to

further secure them in their cell should they become disruptive. To enforce greater isolation on inmates in solitary confinement, telemedicine procedures may be utilized in which medical and mental care is rendered by health professionals via videoconferencing. Any physical or psychiatric issue inmates are experiencing must be displayed or described in order to receive care. Thus, isolated inmates may have few to no meaningful daily interactions with correctional and medical staff who are responsible for their safety and well-being.

In general, two types of isolation are utilized in prisons. The first type, *administrative segregation*, houses inmates who are deemed to be a threat to the security of the institution by penal administrators. Individuals typically housed in this form of solitary confinement include high-profile inmates such as gang leaders, vulnerable prisoners such as sex offenders or juveniles, and those who are persistently violent or are categorized as a high risk of escape. Placement in administrative segregation is based solely on the discretion of correctional administrators and can extend indefinitely. Based on the inmate's behavior, he or she may receive privileges such as a television, literary materials, and opportunities to participate in treatment programs. Disciplinary segregation is reserved for inmates who receive rule infractions. With this type of solitary confinement, the inmate is afforded due process and an opportunity to appear before a disciplinary hearing officer. While this is a time-limited response intended to address violations of institutional conduct regulations, such as flooding one's cell or assaulting a correctional staff member or fellow inmate, this form of isolation may nevertheless extend for years. Compared to administrative segregation, conditions in disciplinary solitary confinement are more severe. Indeed, few, if any, of the aforementioned opportunities available to inmates in administrative segregation are offered to those placed in punitive isolation. Depending on prison policy and the segregated inmate's behavior, this denial of access to privileges may include critically needed mental health care.

Prisoners With Preexisting Mental Health Conditions

Research findings consistently indicate that approximately one third of inmates placed in

isolation struggle with a serious psychiatric disorder. Despite several key legal challenges in which the courts have ruled that placing a mentally ill prisoner in isolation is a violation of the Eighth Amendment to the U.S. Constitution's protection against cruel and unusual punishment clause, no current precedent-setting case law exists banning the practice across all jurisdictions. Citing safety concerns, correctional administrators typically assert that it is prudent to place inmates with mental health conditions in solitary confinement. Within the general prison population, those exhibiting symptoms of a psychiatric disorder are especially vulnerable to victimization. Indeed, some inmates may perceive those openly exhibiting symptoms of such illnesses to be incoherent and incapable of protecting themselves. Consequently, inmates with untreated or undertreated conditions are more likely to be victimized physically, sexually, and even economically. Thus, according to some penal administrators, removing these individuals from the general inmate population and securing them in isolation is the only effective means to ensure their safety and well-being.

While segregating inmates at high risk of victimization may be a prudent protective measure, the empirical evidence suggests that prisoners with a psychiatric illness are more often placed in solitary confinement based on their inability to conform to institutional rules and regulations. Indeed, despite the abundant body of literature documenting the detrimental effects of solitary confinement, the practice of placing these individuals in such conditions remains one of the leading default responses for addressing behavioral issues. Within prisons, custody prevails over treatment. Thus, penal administrators assert that isolation is a necessary option in order to promote safety and security for both inmates and staff. Given the limited budgets and resources with which many prisons must operate, the availability and quality of mental health care varies widely. Inmates with untreated or undertreated mental illnesses are more likely to exhibit unpredictable and violent behavior toward themselves, fellow inmates, and correctional staff. Indeed, research suggests that these individuals are commonly irascible and often refuse to follow directive commands, flood their cells, destroy property, set fires,

smear or throw urine and feces, and engage in a broad range of other disorderly behaviors than their counterparts without mental illness.

The Mental Health Effects of Isolation

As noted previously, over a century of research indicates that solitary confinement exacts a detrimental toll on the psychological well-being of prisoners with and without preexisting conditions. Nevertheless, it is imperative to acknowledge that some empirical evidence suggests that isolation for a period of 60 days or fewer does not promote or exacerbate mental illness among inmates. However, these studies have received criticism based on methodological robustness concerns and the inability to generalize the findings. Indeed, it is the preponderance of the body of literature revealing the egregiously harmful effects of solitary confinement that mental health professionals, researchers, human rights activists, and concerned others cite when advocating for the limited utilization of or abolishment of isolation in prisons for those who struggle with psychiatric disorders.

Given the sensory deprivation exacted in isolation, research indicates that segregated inmates experiencing a mental illness often rapidly become hypersensitive to external stimuli. For example, some report a patent awareness of the sound of lights buzzing overhead, correctional officers' keys rattling, or their own heartbeat. Further, inmates regularly assert that such ordinary noises are amplified to the degree that they are pain-inducing within the confines of an isolation pod. Those with preexisting conditions are especially vulnerable to experiencing florid hallucinations and periods of incoherence. Indeed, the empirical evidence suggests that these states of delirium are often followed by chronic depression, extreme agitation, and paranoia. While in solitary confinement, inmates who experience obsessive thoughts find it challenging to manage frightening or disturbing notions. The extraordinarily restrictive milieu in solitary confinement, particularly as imposed in long-term disciplinary segregation, often contributes to an inmate's inability to manage his or her anger and control his or her impulses.

What is most concerning regarding the impact of isolation that inmates commonly report is a lost

sense of self. Indeed, research suggests that humans are inherently social beings who rely on interactions with others to construct and manage their identity. Absent opportunities to do so, the problem is profoundly compounded for individuals with mental health conditions who may not have had a stable sense of self prior to their incarceration. Thus, absent routine engagement with others, these individuals are denied opportunities for self-development and for cultivating relationships critical to their overall well-being. Consequently, they may find reintegrating into the general prison population especially difficult. Thus, these inmates are acutely vulnerable to being returned to segregation. Further, inmates with preexisting mental health conditions may also confront assorted insurmountable challenges such as interacting with others in an appropriate and prosocial manner in order to reestablish relationships and secure employment. As such, these individuals are at a high risk of recidivating.

Suicide attempts and self-injurious behavior (e.g., banging one's head against cell walls, mutilating or cutting, applying ligatures, ingesting toxins, and swallowing sharp objects) are common among inmates in isolation. Efforts to harm one's self are frequently manifestations of an untreated or undertreated mental health condition such as dysthymia (i.e., chronic or persistent depressive disorder), bipolar disorder, or schizophrenia. Indeed, research findings suggest that inmates with preexisting mental health conditions are approximately 7 times more likely to engage in self-injurious behavior or attempt suicide than those without psychiatric disorders. While correctional administrators and staff may perceive such behavior as symptoms of an inmate's psychiatric disorder, the individual may nevertheless receive disciplinary infractions following episodes involving self-injury or suicide attempts. The rationale justifying this response is that, because inmates are in state custody, any harm that they exact on themselves may be deemed destruction of state property. As such, disciplinary infractions incurred based on self-harm may extend an inmate's time in the very isolation that may be contributing to the decline in his or her mental health. Suicide is a persistent concern for correctional administrators and staff. Research indicates that fatal self-harm is the leading cause

of death among those incarcerated. Although findings vary, some empirical evidence suggests that half of all completed suicides among inmates occur while they are consigned to solitary confinement.

Inmates with untreated or undertreated psychiatric disorders commonly struggle to conform to society's laws and behavior expectations, so perhaps it is unsurprising that they are frequently incapable of abiding by institutional rules and regulations within the often volatile milieu of a prison. While it is imperative to be mindful of the critical interest of penal administrators in providing and maintaining a safe and secure environment for inmates and staff, the extensively documented mental health effects associated with isolation, particularly for inmates with preexisting psychiatric issues, raise considerable concerns regarding this correctional measure. While calls for reform to limit or abolish isolation in America's prisons for these particularly vulnerable individuals grow, the challenge to identify and implement a more humane alternative practice that more readily meets the needs of all concerned remains.

J

JAIL DIVERSION

Jail diversion programs are prebooking or post-booking interventions aimed at decreasing the involvement of persons with serious mental illness (SMI) or co-occurring substance use disorders (COD) in the criminal justice system and channeling them into community-based treatment and other services. They are considered a *diversion from* typical criminal justice prosecution and sentencing and *into* community-based programs that can better meet the needs of offenders with complex behavioral health needs. Diversion may occur early in the justice processing, such as at arrest, or later by diverting an individual convicted of a crime from a jail or prison term and into a community program. This entry provides an overview of the development and expansion of jail diversion, examines the opportunities, or intercepts, for diversion, then explores research findings on the effectiveness of this practice.

Development of Diversion

Jail diversion programs arose from the recognition that typical criminal justice processing of persons with SMI or COD was unsuccessful in slowing the revolving door of offending, arrest, incarceration, release, and reoffending. Moreover, it was recognized that it led to avoidable costs for unnecessary jail days. Jail diversion programs were developed to address these challenges. Justice-involved individuals with SMI and COD require significant

services and supervision whether they are incarcerated or living in the community. Annually, over 2 million people, approximately 15% of men and 31% of women, entering U.S. jails have an SMI, between 50% and 100% of this group has a COD, and nearly all have significant trauma histories. Most jails are not equipped to provide intensive, individualized treatment for this population whose treatment needs include mental health, substance use, trauma, and more general habilitation such as housing and employment. While some jails in large metropolitan areas have extensive mental health services, most jail detainees are in small, local jails that do not have the staff or resources to provide appropriate evidence-based treatment. Jail diversion programs partner with community providers who are able to meet the significant treatment needs, while at the same time providing a reduction in criminal recidivism.

Expansion of Jail Diversion

The U.S. federal government has invested resources into jail diversion programs through the Department of Justice's Justice and Mental Health Collaboration Project. The Substance Abuse and Mental Health Services Administration promoted diversion through Targeted Expansion Jail Diversion, Jail Diversion Trauma Recovery, Early Diversion, Adult Treatment Court Collaborative, and the Behavioral Health Treatment Court Collaborative grant programs. These federal initiatives gave communities the funding to pilot programs to target the expansion of jail

behavioral health services, develop treatment courts, and establish reentry programs. Once communities established their new programs and were able to use evaluation data to confirm their success, they had leverage to obtain financial and political support to continue beyond the life of the federal funding.

Opportunities for Diversion

There are many points in traditional criminal justice processing where diversion opportunities occur. The Sequential Intercept Map provides a model for communities to target interventions to reduce the dual burden of difficult, resource-intensive detainees as well as the unnecessary justice involvement for this population. By examining where in the justice system there are evidence-based resources and significant gaps, communities can develop and implement successful jail diversion programs for people with SMI and COD. At each intercept, services must be available in the community for diversion to occur. Just as important, professionals working in the justice, treatment, and public health systems must know what programs exist and collaborate across the systems.

Intercept 1 is law enforcement and other first responders. Whether it is a result of proactive policing or in response to a call from the community, police and emergency services professionals can divert someone from the justice system into a community alternative in lieu of arrest. The purpose of these diversion programs is to disrupt deeper justice system penetration, protect the public, and funnel people into treatment. An example of an Intercept 1 diversion program is the police Crisis Intervention Team (CIT), which provides police with tools to identify persons in need of mental health or substance use treatment, de-escalate often tense situations, and transport individuals to a safe treatment alternative rather than arrest them and take them to jail. For CIT to work in a community, police must work with other emergency services professionals, including dispatch and EMTs, and with the community-based behavioral health service providers. Police must have an alternative available to them other than transporting an individual to the jail or simply releasing him or her.

Intercept 2 is the initial detention and hearing that follows an arrest but before a plea has been entered. Diversion programs at this intercept require considerable coordination across the justice system, including the jail staff, prosecutor, defense counsel, pretrial services, probation, and the courts. When a person with SMI or COD is booked into the jail, there is an opportunity to screen for mental health, substance use, trauma, and suicide risk. While the individual has been arrested and booked, a diversion intervention at this point is available in some communities. For example, specialized intensive probation is a type of diversion in which probation officers have specialized training in mental health and/or substance use disorders and a reduced caseload. The prosecutor, defense, and court must agree to set aside the typical next steps of plea and sentencing to allow the community-based program to take over the case. In many communities, this is an *adjournment in consideration of dismissal*. Probationers typically must report to their probation officer more often than in traditional probation, and treatment is frequently a requirement. If the individual completes the conditions, the charges are dismissed. If not, he or she is further processed in the justice system.

Intercept 3 jail diversion programs include problem-solving courts such as drug courts, mental health courts, family drug courts, DWI courts, youth courts, and veterans' courts. These court diversion programs intend to reduce further justice involvement through court-supervised community-based treatment; as a group, they are often referred to as *treatment courts* since mandated treatment is a common characteristic across all types. While there are some pre-plea treatment courts, most are post-plea in which the offender must enter a guilty plea to be eligible for the intensive supervision and community-based treatment that accompanies such programs.

Drug courts in particular have proliferated throughout the United States at the municipal and county level with substantial financial resources committed through both the federal and state governments. Mental health courts are not as widespread as drug courts, in part, because they have not received significant federal or state funding. While there is considerable variation across types of treatment courts and jurisdictions, they share

some common features: a separate court docket; a court team that includes a judge who presides over status hearings, a prosecutor and defense attorney, treatment providers, probation, and increasingly a peer; a collaborative versus an adversarial approach; judicial supervision through regular status hearings; voluntary participation from defendants; use of incentives and sanctions; and dismissal of charges upon successful completion of program requirements.

Intercept 4 diversion occurs at reentry from either prison or jail. Programs at this intercept provide intensive wrap-around services and supervision for persons with SMI and COD who are leaving jail or prison. This population is often at high risk of reoffending, and diversion programs aim to disrupt the recidivism process by identifying needed services and putting them in place prior to, or immediately following, release. The justice and treatment systems prevent reoffending and reincarceration through linkage to community-based treatment and intensive justice supervision. Intensive Case Management was the first reentry model developed; it was largely based in the behavioral health services system. It includes smaller than typical caseloads, more frequent contacts with the individual, and an array of treatment programs. Two additional diversion programs at this intercept are Assertive Community Treatment and Forensic Assertive Community Treatment. They are similar to Intensive Case Management in that they focus on small caseloads and collaboration among many community-based treatment providers along with crisis intervention. Intensive Case Management, Assertive Community Treatment, and Forensic Assertive Community Treatment are generally targeted for persons leaving jail, and in some communities, the community linkage is established as part of the prerelease planning, sometimes called *in reach*. Similarly, individuals with COD and SMI leaving prison may receive significant prerelease planning to assist their transition into the community.

Intercept 5 jail diversion is the most common type of jail or prison diversion in that it includes probation (i.e., jail diversion) and parole (i.e., prison diversion), often referred to as *community corrections*. More individuals are under community supervision in the United States than in jails and prisons combined, with approximately 5

million men and women on probation or parole. A significant portion of the community corrections population has SMI or COD. For the reentry of these individuals to be successful (i.e., they do not reoffend), communities need evidence-based programs ready and available. People with SMI and COD have behavioral difficulty while incarcerated, especially if their mental illness is undiagnosed or untreated. They often have many behavioral infractions that lead to additional incarceration time; they are rarely released early. In addition, they are more likely than others to have their probation and parole revoked for technical infractions rather than new offenses. A diversion program at the community corrections stage would include specialized probation and parole. Similar to other forms of community-based diversion programs, these include reduced caseloads, specially trained officers, and a focus on treatment compliance. Rather than revoke probation or parole for an individual on this type of diversion program, it is more likely that the officer would work with treatment providers and the court to increase compliance.

Research on Jail Diversion

Overall, research on jail diversion programs supports the claim that community-based programs are more successful at reducing continuing criminal justice involvement for persons with SMI and COD than traditional interventions. All jail diversion programs that partner with community-based behavioral health treatment providers have an increase in treatment involvement. The research is less convincing, however, that programs improve clinical outcomes, despite the increase in treatment services.

CIT policing is one of the most popular early diversion programs adopted by police departments. By providing officers with 40 hr of training, communities can expect a reduction in the number of persons with SMI and COD who are arrested for minor infractions such as disturbing the peace. Another outcome of CIT is that there are fewer police officer injuries and less aggressive policing toward SMI and COD populations. Effective CIT police departments are typically more aware of treatment resources and have partnered with providers to address the needs of the

justice-involved population with SMI and COD. Despite wide program variability, CIT is associated with overall positive outcomes.

Less is known about the impact of postarrest/prebooking diversion programs (perhaps because they are fewer in number). Because diversion at this point requires cross-system collaboration, such programs are more difficult to develop and implement, often due to inconsistency and change among key personnel. More research needs to be conducted on these programs to measure their effectiveness in meeting the diversion goals.

There is considerable evidence that treatment courts are effective in reducing criminal justice involvement of participants. Overall, drug courts and mental health courts show a reduction in jail days and arrest for participants, especially individuals who complete the court-mandated conditions and *graduate*. In addition, courts are successful in getting treatment for participants, with evidence showing that they are more likely to engage in treatment when supervised by the court. What has been challenging is establishing guidelines for what constitutes a treatment court and making sure that communities have available evidence-based services. Some states have created and monitor these programs to reduce variability from jurisdiction to jurisdiction, despite each having their own community and personnel characteristics. Community-based diversion programs (e.g., reentry, probation, parole) typically show improvements in criminal justice outcomes through fewer arrests, fewer jail days, and a longer time gap before reoffending.

Final Thoughts

Across the criminal justice system, diversion programs must be tailored for specific populations, including attention paid to individual characteristics. There is no *one-size fits all* approach. Also, communities may consider designing and implementing programs with collaboration across the spectrum of services that are necessary for success including justice, treatment, public health, social services, housing, employment, and more. Cost studies of diversion programs demonstrate that while there is a savings in reducing arrests and jail days, for example, there is a corresponding increase in treatment expenses. Diversion is a community

approach and requires cross-system commitment of resources.

JAIL SCREENING ASSESSMENT TOOL (JSAT)

The Jail Screening Assessment Tool (JSAT) is a set of questions designed to determine mental health needs of newly admitted inmates and identify those prisoners who need mental health treatment or pose a risk to themselves or others. By identifying those individuals in need of mental health treatment upon intake, the JSAT can aid with efficiently determining appropriate placement and effective treatment locales and programs for entering inmates. First developed in Canada in 1991, this tool has been adopted successfully in correctional settings in such additional countries as the United States and Australia. This entry first provides an overview of mental disorders and mental health screenings in correctional settings; then, the entry focuses on the JSAT: its key characteristics and research evidence.

Mental Disorders in Correctional Settings

The overrepresentation of individuals with mental disorders in correctional settings is an international

public health problem. There are approximately 10 million prisoners worldwide and as many as one in seven inmates with psychosis or major depression. Moreover, up to three-quarters of inmates have primary or comorbid (in conjunction with other medical issues) substance use disorders. A systematic review of studies published between 1966 and 2010 (33,588 prisoners, 81 publications, 109 samples) across 24 countries concluded that the rates of psychosis (men = 3.6%; women = 3.9%) and major depression (men = 10.2%; women = 14.1%) have not changed substantially across the 40-year period, with the exception that the rate of depression has increased in U.S. prisons.

Many correctional facilities are ill-equipped to serve people with mental disorders. Inadequate care contributes to increased risk of institutional incidents that might put the safety of inmates and staff at risk of harm (e.g., inmates with mental disorders are at higher risk to violate rules, engage in self-harmful behavior, and are more vulnerable to physical and sexual abuse while incarcerated) and is known to lead to elevated staff stress, sick days, and turnover. In the absence of appropriate care and discharge planning, the transition back to the community is a particularly risky period for suicide, return to substance use with an increased possibility of overdose, recidivism, and other challenges common to marginalized populations (e.g., homelessness). Furthermore, most inmates are released to the community (50% within 3 years), and some estimates note that up to 50% return to correctional facilities within 3 years of release. Recidivism rates for offenders with mental disorders exceed those of individuals from the general prison population. Thus, addressing mental health needs may not only help ease the transition of prisoners to the community but also help reduce reoffending and associated economic burdens.

Substantial advances have been achieved in responding to the recognized need to advance standards of care in the provision of mental health services in jails and prisons. In North America, these developments have been spearheaded by the work of organizations such as the American Psychiatric Association, the Treatment Advocacy Center, National Commission on Correctional Health Care, and the Federal-Provincial-Territorial Heads of Corrections Working Group on Mental Health and Mental Health Commission of

Canada. These standards consistently recommend a continuum of care, of which mental health screening is considered a key element.

Mental Health Screening in Jails

Jails are generally the gateway into the criminal justice system. Although the distinctions are sometimes fuzzy, jails typically house individuals who have been arrested and are remanded to be held while awaiting a plea agreement, trial, or sentencing; jails also house individuals serving short sentences, whereas inmates who are convicted, generally sentenced to more than 1 year, are detained in prisons (also known as penitentiaries). Jails often are the initial point of contact with mental health providers for many mentally disordered inmates. A considerable number of people arriving at a jail are actively or recently intoxicated, arrive with injuries from fights or assaults, and/or are mentally ill with no other place for law enforcement to deliver them. This makes the intake process challenging for the jail's staff and its medical personnel. Jails thus provide an important public health opportunity for implementing innovative and comprehensive systems of care. Systematic screening for mental health needs in jails is the essential first step.

Mental health screening in jails can accomplish several core objectives: (a) redirect severely mentally ill individuals out of the criminal justice system and into more appropriate settings and diversion programs; (b) ensure that other less acutely ill individuals receive the care and services they require while they are housed in correctional settings; (c) prevent violence and other disruptive incidents which, in turn, would reduce stress and injuries for inmates and staff; and (d) support release planning with the goal of improved quality of life for the individuals, reduced recidivism, and substantial public health benefits, including reduced economic burdens.

Mental health screening should occur as early upon admission to a correctional facility as possible, typically within the first 24 hr. Ideally, the mental health screening process includes a brief review of any available file information, consideration of any collateral information (e.g., from correctional staff who interacted with the inmate during admission or transport), and a face-to-face

interview with the inmate. Where relevant and possible, mental health records should be accessed and the inmate's general practitioner should be consulted. Interviews should take place in a reasonably private interview room where the interviewer is also provided with safety measures.

Key Characteristics of the JSAT

A trained interviewer can complete a JSAT interview in approximately 15–20 min for male inmates and 25–30 min for female inmates (women tend to contextualize their circumstances and articulate the trajectory that brought them to their current circumstances) and those with more complex needs (e.g., a combination of current psychiatric symptoms and substance abuse withdrawal or risk of harm to self/others). The JSAT is not a standardized psychological test and thus can be administered by nonlicensed professionals provided they have the requisite expertise in mental health. Typically, sites have employed graduate students in clinical psychology, psychological interns or psychiatric nurses, forensic case workers, or social workers to complete the screening interviews.

Intake interviewers/screeners do not wear uniforms and clearly communicate that although there are limitations (e.g., threats of suicide or violence), the information they collect is kept confidential and not shared with correctional officers. Assurances about confidentiality and advising the inmate that the purpose of the interview and the collection of the information is to help make their admission and stay at the institution as smooth and safe as possible can help develop rapport and facilitate open and honest conversations.

The JSAT manual provides a semi-structured interview (e.g., Do you have a history of aggression/violence?) and additional prompts (e.g., Have you ever been told you have an anger management problem? Do you sometimes kick or hit things when you get frustrated or angry?). The information is collated on a double-sided, legal-sized, copyright-protected form (note, there are no fees to implement the form beyond the initial purchase of the manual) or can be integrated into the inmates' electronic health records, which can be useful for tracking population profiles and supporting quality research and evaluation initiatives.

The JSAT screening interview and summary form prompt screeners to collect data in the following categories:

- a. identifying information and demographics (e.g., age, language, ethnicity/cultural identity)
- b. social background (e.g., marital status, relationship stability, living situation, social support, financial support, family support, children, and education)
- c. previous and current legal status (e.g., prior incarcerations, current charges, current legal status)
- d. violence issues (e.g., past violent offenses, prior institutional charges, current anger level)
- e. substance use (e.g., tobacco, alcohol, drug(s), methods of use, treatment, including methadone/suboxone)
- f. recent or past mental health treatment (e.g., prior psychiatric hospitalization, current medication needs)
- g. current mental health status (supported by a modified version of the Brief Psychiatric Rating Scale)
- h. suicide/self-harm issues (e.g., prior attempts, including those while in custody, method/lethality, current ideation, current plans)

In addition to these domains, the screening procedure also includes completion of a revised version (4.0) of the Brief Psychiatric Rating Scale. This section consists of 14 items coded (i.e., assessed and recorded) on the basis of the patient's self-report (and behavior) during the interview (e.g., anxiety, depression, bizarre behavior, self-neglect) and 10 items coded on the basis of the individual's behavior and speech during the interview (e.g., grandiosity, uncooperativeness, motor hyperactivity). Based on early feedback, the JSAT authors revised the 7-point rating scale on the Brief Psychiatric Rating Scale to a 3-point scale (*present*, *possible*, *absent*) to support inter-rater reliability (i.e., the extent to which discrete interviewers come to consistent decisions) and to increase the efficiency of the interviews (i.e., reduce the per-inmate time required to complete the JSAT).

The screeners use this information to evaluate risk of adverse events common to correctional settings (e.g., suicide, self-harm, violence, and victimization), make management recommendations (e.g., mental health referrals, placement in a mental health unit, protective custody), or refer the inmate for a more comprehensive mental health assessment (typically with a mental health coordinator initially, or psychology, psychiatry). This requires clear communication and documentation protocols so that urgent safety and security needs are shared with correctional staff in a timely manner, recommendations for placement within the jail or other specific accommodations are considered by the appropriate personnel, and referrals for mental health follow-up are made efficiently (e.g., referral for medications). These decisions are made using structured professional judgment, a guided clinical approach to decision-making without fixed and explicit rules but which is based in part on the standardized information gathered from the JSAT interview.

Given that the JSAT is a screen for mental health and management needs, the preference is to err on the side of caution to ensure that individuals with mental health needs and/or individuals who might present a risk of harm to self or others, or victimization, are not overlooked. It can be difficult to evaluate risk and to discern serious mental health concerns from situational distress and/or substance use withdrawal in a brief interview, so the manual recommends that screeners be overly inclusive when uncertain (i.e., overrefer rather than underrefer). Optimally a brief check-in can be done the following day with inmates who were referred for mental health services. The objective is to touch base with inmates who may have settled well after the initial stress of admission; often inmates will drop off the referral list as a result.

Research Evidence

The JSAT has been evaluated in four studies in British Columbia, Canada, and one in Melbourne, Australia. An early study with male inmates revealed a high rate of agreement between intake interviewers' assessments and independent evaluations with the Structured Clinical Interview for DSM (SCID). The JSAT exhibited a sensitivity or true positive rate of 84%, meaning that 84% of

individuals identified as having mental health needs did, in fact, have a mental disorder. Conversely, 67% of individuals who did not have a mental disorder were correctly identified as such, also called the *specificity* or *true negative rate*.

When testing the JSAT in a sample of women admitted to a Canadian federal institution against comprehensive assessments completed using the SCID for *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* Axis-I Disorders—Non-Patient Edition, intake interviews had a sensitivity (i.e., true positive rate) of 70.6% and a specificity (i.e., true negative rate) of 75.0%. The false-positive rate was 29.4%, meaning that 29.4% of the individuals who had been assessed as having mental health needs with the JSAT were not diagnosed with a mental disorder when assessed with the more comprehensive SCID. The false-negative rate was 25.0%, meaning that one fourth of the individuals who were assessed as not having a mental disorder did, according to the SCID assessments. The positive predictive power was 64.3% (i.e., the proportion of positive test results that were actually from people who had a mental disorder according to the SCID) and the negative predictive power was 80.0% (the proportion of people with negative test results who actually did not have a mental disorder according to the SCID). Finally, as would be expected (given the low base rate of severe disorders such as schizophrenia), very few of the women were identified as *severely* mentally ill, with just 1% of female inmates identified as being in need of transfer to a secure mental health facility.

A third Canadian study, sampling 106 inmates in British Columbia screened randomly and in a counterbalanced fashion, demonstrated that the Brief Jail Mental Health Screen had better sensitivity, while the JSAT had better specificity across most definitions of mental disorder. Findings from an Australian study with 150 detainees in police cells demonstrated that the JSAT performance was similar to the Brief Jail Mental Health Screen in identifying seriously mentally ill individuals but superior in terms of identifying Axis-I disorders (i.e., all psychological diagnostic categories except mental retardation and personality disorder; however, the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, published in 2013, did away with the Axes) with the exception of substance use disorders. The JSAT identified all

inmates with a diagnosis of schizophrenia, bipolar disorder, depressive disorder, and almost all of those with an anxiety disorder (92.3%).

The evidence to date suggests that the JSAT is an efficient, valid, and reliable means of screening for mental disorder and making placement and treatment recommendations in correctional populations. Additional research is needed, however, to further examine clinical utility, particularly with respect to unique subgroups (e.g., women, ethnic minorities, and across cultures).

JAILS

Jails are municipal or county-level facilities designated for the confinement of individuals who have been arrested and, in most cases, are unable to afford bail and are awaiting trial or, less commonly, have already been sentenced to a term of imprisonment

and are actively serving that sentence. Although most people charged with a crime are booked in jail and released within hours or days, jails in most states allow for the confinement of those serving sentences of up to a year. Some states commonly house people serving state prison sentences in county jails through various work-release programs for terms of usually 1–5 years, and in rare cases, people awaiting trial for more serious charges may spend years in pretrial detention.

As the entryway to incarceration, jails are a critical juncture where key decisions are made that are likely to shape the trajectory for years to come for those who enter their doors. However, jails are often not equipped to appropriately deal with the myriad issues affecting people who reside in them. Likewise, those who are arrested often find their lives significantly disrupted and lack the capacity to make informed key decisions. Crises are common in jails, and most facilities are poorly equipped to provide adequate crisis intervention services. This entry provides an overview of the history of jails, a portrait of their populations, and concerns about the jail system.

History

The first use of a jail in the United States can be traced back to 1632 with the construction of a “People Pen” in prerevolutionary Boston. From this time until shortly after the American Revolution, jails served as a place for holding people awaiting trial, and for others, the meting out of punishments was already imposed. Punishments for serious crimes often resulted in hangings, whipping, branding, and maiming, while less serious crimes resulted in punishments aimed at humiliation, such as the use of stocks and pillories, or the use of the ducking stool (i.e., strapping a person to a chair fastened to the end of a pole and plunging that person [usually a woman] repeatedly into a pond or river). Incarceration in jail as a form of punishment itself—measured in days, months, or years—did not exist until the conversion of Philadelphia’s Walnut Street Jail in 1790. The addition of 16 solitary wings to the jail reflected the prevailing Quaker belief that solitary reflection would lead to remorse.

Throughout the 19th century, states and localities increasingly shifted more toward incarceration as the primary means of punishment and away

from corporal punishments. Not every jurisdiction had jails, however, so the type of punishment often depended on available measures. It wasn't until the early 20th century that jails began to proliferate across the country.

As of 2018, there are over 3,300 jails in the United States holding approximately 730,000 people. The number of people detained in jail at any given time, however, drastically underestimates the number of people revolving through its doors. In recent years, jails have recorded over 11 million jail admissions annually, with many people returning multiple times each year.

Portrait of the Population

Jails house some of society's most vulnerable groups. Although men make up almost 90% of all those in jail, the female jail population has, in recent years, been the fastest growing segment of the American jail population. Jails have a disproportionate effect on virtually every disadvantaged group in the United States.

Race and Ethnicity

African Americans and Latinos collectively make up more than half of all people in jail. Despite constituting only 13% of the U.S. population, African Americans make up about 35% of those incarcerated in U.S. jails, a rate 4 times that of Caucasian and 3 times the rate of Latinos. These disparities vary by jail size and geography with larger jail systems such as Rikers Island in New York City and jail systems in Los Angeles County and Cook County, IL, having much wider disparities between African Americans and Whites than smaller jails in more rural areas. The average stay in jail also varies greatly by race, particularly for African Americans who spend an average of 2 weeks longer in jail longer than Caucasian. Although Native Americans make up only a small portion of those in jail, they have rates of overrepresentation similar to those of African Americans. Asian Americans are underrepresented in jails.

Education, Employment, and Income

Almost half of all those in jail do not have a high school diploma or GED. Many did not finish

school either because of academic or behavior problems, because they were incarcerated, or for economic reasons. Given their low levels of educational attainment, it is not surprising that people in jail have a high prearrest unemployment rate. A little more than half of all those in jail were gainfully employed at the time of their arrest, with only a minority earning above-poverty-level wages. Those with low educational attainment and low (or no) incomes are also more likely to stay in jail longer since they are often unable to make bond.

Mental Illness

The prevalence of mental health problems has existed among people in jail since the deinstitutionalization of patients with mental illnesses from state psychiatric hospitals during the 1970s. Jails, by default, have become de facto mental health facilities. The three largest institutional providers of mental health services in the United States are, in fact, jails: Los Angeles County, Rikers Island in New York, and Cook County. About 14% of people in jail have a serious mental illness, a rate about 4–5 times higher than in the general population. Individuals with serious mental illnesses are much less likely to receive mental health screening or treatment once in jail and are also more likely to be punished and placed in solitary confinement. People with mental illnesses are also at significantly high risk of victimization and self-harm. Once placed in jail, those who were being treated for their mental illnesses before their arrest, at best, experience at least a temporary interruption in their care and, at worst, a complete discontinuation of their care and a worsening of their mental health conditions.

Substance Use

About two thirds of those in jail have a substance use disorder, while three quarters of those in jail with a serious mental illness have a co-occurring substance use disorder. Women in jail are far more likely to have a substance use disorder than men, although the rate is high for both genders. Alcohol, marijuana, and cocaine are the three most commonly abused substances among men and women who enter jail. Women in jail with substance dependency also have experienced higher rates of sexual abuse than women without

substance dependency. The relatively short periods of time people spend in jail combined with security-oriented staff not trained in providing therapeutic services do not make jails optimal facilities for mental health or substance abuse treatment.

Crimes

About three quarters of all people in jail are incarcerated for nonviolent drug, property, or public order offenses, such as driving while intoxicated or traffic offenses. Most people in jail—about half a million—are in pretrial detention but unable to pay their bail and thus are legally innocent. About a quarter of all those in jail are charged with violent offenses, with assault charges being by far the most common violent offense. Only a small percentage of people in jail are charged with more serious violent crimes such as murder, rape, or sexual assault. Since jails are localized facilities, they are often reflective of their surrounding communities' enforcement priorities and political dynamics, which can vary greatly by region.

Common Concerns

Criminal justice advocates, attorneys, and mental health experts are concerned about inhumane conditions and a lack of treatment services in jails, while politicians and government officials are concerned with the costs of detaining millions of people in jail each year with little to no positive outcomes. Although many people disagree with how best to address these concerns regarding jails, on a number of issues, a broad consensus exists that changes need to occur.

Overcrowding

A primary issue facing jails is overcrowding. People in jails throughout the country are often forced to sleep on floors due to a lack of available beds. Some jurisdictions have addressed overcrowding in their jails by lowering the bonds of many nonviolent offenders, hoping to decrease the number of people stuck in jail simply because they cannot afford bail. Others have sought to reduce penalties for offenses (e.g., California's Proposition 47 downgraded many drug and property crimes from felonies to misdemeanors). Led by California's criminal

justice realignment laws adopted in 2011, states have increased the use of split sentencing, allowing people to serve part of their sentence in jail and part under community supervision. Many counties are also increasingly experimenting with evidence-based problem-solving courts such as drug or mental health courts both as a jail diversion program and as a means of addressing the underlying issue that contributed to the criminal behavior in the first place. Although some jails appear to have had some success with these measures, jail overcrowding remains a problem in virtually every jail in the United States.

Suicide

Suicide is the leading cause of death among people in jail, accounting for about one third of all jail deaths annually. Smaller jails have higher suicide rates than larger jails, likely because larger jails are better equipped to be proactive with suicide prevention measures than smaller jails with fewer staff and resources. Scholars have called on jails to follow recommendations commonly set forth in psychiatric hospitals for suicide prevention, including training programs, screening procedures, communication, and documentation as a way to curb these high suicide rates. Still, around 300 people commit suicide in jail each year.

Solitary Confinement

Solitary confinement (i.e., the placement of individuals in isolation, devoid of human contact except with corrections staff) is perhaps the most extreme form of punishment in jails. While less than 3% of those in jail are housed in this manner on a given day, about 1 in 5 will spend some time in solitary before he or she leaves jail. A disproportionate number of people in solitary confinement have some form of mental illness, placing them at increased risk of worsening mental health symptoms, such as anxiety and post-traumatic symptoms. Many jails have come under heavy criticism for systemically housing gay and transgender people in solitary confinement, increasing their risk of self-harm.

Financial Costs

The cost of incarcerating 730,000 people each day in jail costs over US\$20 billion annually, or

about US\$31,000 per person. Personnel costs, contracts, and utilities make up the vast majority of jail expenditures with only a tiny fraction allotted for treatment services for people with mental health or substance use issues. The skyrocketing cost of jails can be attributed in large part to the average length of stay. Since 1983, the number of people in jail has tripled as the average stay has increased from 14 to 23 days, while the cost per inmate has stayed relatively the same.

Negative Consequences

Going to jail—even for a short period of time—has adverse consequences that extend well beyond release. Millions of people each year experience a combination of negative effects, including the interruption of mental health treatment, a disruption to their families resulting from their absence, the loss of jobs, and the associated stigma that often follows an arrest or conviction. These effects have a significant influence on those adjusting to the rigors of a highly structured jail environment, increasing their stress and anxiety and worsening preexisting mental health symptoms for many. Spending time in jail, especially an extended period of time, can also lead to a loss of Social Security Income or Social Security Disability Insurance, causing significant financial strain for those ordered to pay fines by the court. This often creates a revolving door of people who return to jail shortly after having left it since they are in worse mental and financial shape than when they entered the first time. This rapid turnover of people in jails makes any type of service provision or discharge planning incredibly difficult. Being detained in jail, regardless of the outcome of the charges, increases the risk of homelessness afterward.

JUVENILE DELINQUENCY AND ANTISOCIAL BEHAVIOR

Juvenile delinquency is the breaking of the criminal code by a person who is not an adult (an individual under the age of 17 or 18 years in most U.S. jurisdictions). Individuals qualifying as juveniles are processed in the juvenile court system. This can include offenses considered to be criminal offenses for adult offenders (e.g., theft, assault, murder) or behaviors prohibited for juveniles, known as *status offenses* (e.g., truancy, running away, breaking curfew, underage drinking). This entry provides a brief overview of relevant statistics on justice-involved youth and rates of recidivism (i.e., reoffending) and history of the juvenile justice system as well as developmental theories regarding antisocial behavior in adolescence and psychological disorders relevant to juvenile delinquency and antisocial behavior. Finally, this entry ends by briefly discussing the Risk-Need-Responsivity (RNR) model in justice-involved youth.

Relevant Statistics

According to the Federal Bureau of Investigation's 2017 Unified Crime Report, 545,420 persons

under 18 years were arrested in the United States in 2017; 71% of these arrests were male juveniles. Juvenile arrests made up approximately 8% of all arrests and approximately 11% of all violent crime arrests in 2017. Recidivism is a repeated criminal behavior and is used to track chronic offenders. There is no information on national rates of juvenile recidivism due to data not being available in all states, differences in how recidivism is defined, differences in length of follow-up, or failure to follow juveniles into the adult criminal justice system. However, information gained from various large-scale studies suggests that few juveniles who commit violent crimes recidivate and most justice-involved youth do not become adult offenders.

History of Juvenile Justice System

The juvenile court system in the United States as it is known today is relatively new. Prior to the 20th century, aberrant youth were tried and sentenced as adults. In the early 20th century, reformers called for a distinction between youth and adults in the criminal justice system, appealing to the *parens patriae* (Latin for *parent of the country*) model of criminal justice in which the government functions as a legal protector of those who cannot protect themselves. Under this approach, the government would separate juvenile offenders from adult offenders in order to allow youth offenders to receive treatment and rehabilitation instead of punishment. This rehabilitative approach to juvenile justice persisted until the 1960s when reformers called for significant changes to the juvenile justice policy. These were eventually ushered in by several seminal U.S. Supreme Court decisions.

Until this point, although the rehabilitative model of juvenile justice had emphasized care and treatment of juvenile offenders, the *parens patriae* approach led to discrepancies in juvenile and adult rights when undergoing court proceedings. For example, juveniles lacked due process rights, which provide equal protection under the Fifth and Fourteenth Amendments to the U.S. Constitution. These rights protect individuals from unfair or unjust treatment by the justice system by including safeguards for individuals involved in criminal or civil procedures.

In *Kent v. United States* (1966), Kent (a longtime juvenile offender) was certified to criminal court jurisdiction at the age of 16 years without a full investigation in juvenile court and despite the protests of his defense attorney. He was then sentenced to 30–90 years in prison. The defense attorney appealed the decision because his client had not been granted a formal hearing in juvenile court for waiver to criminal court. As a result, the Supreme Court ruled that juveniles are entitled to protection under due process while in juvenile court. A second Supreme Court decision, *In re Gault* (1967), expanded a juvenile's right to due process. Specifically, this case codified a juvenile's right to confront and cross-examine witnesses, right against self-incrimination, right to written notice of charges, and right to legal representation.

At the same time these landmark decisions were providing more equal protection under the law for juvenile offenders, public perception of juvenile crime was shifting. The 1970s and 1980s saw an increase in juvenile-perpetrated crime, and with it, public perception swayed to favor increased punishment (as opposed to rehabilitation) for juvenile offenders. Specifically, public policy shifted to lower the age at which juveniles could be transferred to adult court, broadened the types of offenses that could result in transfer, and created automatic transfer statutes for certain offenses. This resulted in more juvenile offenders being tried and sentenced as adults in the late 20th century.

Near the beginning of the 21st century, juvenile crime rates again began to fall, and the pendulum began to swing in favor of a more rehabilitative focus for juvenile justice proceedings. In addition, new findings from fields such as developmental psychology and cognitive neuroscience began to highlight fundamental differences in the adolescent brain in terms of decision-making capacity, peer influences, and emotion regulation and subsequently provided a scientific rationale for a rehabilitation-focused juvenile justice system including a renewed conviction that adolescents should be treated fundamentally different than adult offenders. For landmark cases involving research on developmental psychology and developmental neuroscience, see *Roper v. Simmons* (2005), *Graham v. Florida* (2010), *Miller v. Alabama* (2012), and *People v. Caballero* (2012).

Theories of Juvenile Delinquency and Antisocial Behavior

There are several major theories of juvenile delinquency and antisocial behavior, which are consistent with developmental psychology and supported by research. A theory proposed by Terrie Moffitt posits two distinct types of offenders: adolescent-limited and life-course persistent (LCP). For adolescent-limited offenders, delinquent behavior arises during the teenage years and is not present during childhood or adulthood. For LCP offenders, antisocial behavior can be seen at an early age (approximately aged 3 or 4) and evolves into delinquent behavior in adolescence; then, instead of diminishing in late adolescence, delinquent behavior evolves into criminal activity and persists throughout the life span. Prenatal and postnatal neurological problems (e.g., higher rates of attention-deficit/hyperactivity disorder and learning disorders) are more common within LCP offenders.

An important question regarding juvenile delinquency and antisocial behavior is: "How many juvenile offenders continue to commit crimes into adulthood"? Consistent with Moffitt's theory, most delinquent offenders discontinue antisocial behavior in their late adolescence or early adulthood. Although LCP offenders account for a disproportionate number of delinquent acts, adolescent-limited offenders represent the majority of juvenile offenders; LCP offenders likely make up only 5–10% of male and less than 2% of female juvenile offenders.

Another well-supported developmental theory of juvenile delinquency and antisocial behavior articulated by Laurence Steinberg is the Developmental Dual Systems Model. Steinberg cites neuroimaging studies of structural, functional, and neurochemical changes within the brain during adolescent development. Therefore, he proposes two systems of the brain to explain risk-taking increases between childhood and adolescence and decreases between adolescence and adulthood. The socioemotional system of the brain is related to increased risk-taking, sensation seeking (i.e., tendency to seek novel and sometimes risky experiences), impulsivity, and sensitivity to peer influences. The socioemotional system rapidly matures during early adolescence and is fully matured by late adolescence. The cognitive control system is involved in

self-regulation (i.e., the ability to stop and regulate impulsive behaviors) and future orientation (i.e., the ability to consider future outcomes in a way that impacts present decision-making). The cognitive control system begins to mature in late adolescence and is not fully mature into early adulthood. Thus, Steinberg proposes the *imbalance* between the brain's emotion and control systems' accounts for the increased rates of not only delinquency but also general risk-taking and the greater impulsive behaviors observed in many adolescents (e.g., risky substance use, sexual behaviors). The age-crime curve serves as a representation of this bell-shaped relationship between age and delinquent involvement and shows the progression of offending peaking around mid- to late adolescence. Because the role of the cognitive control system is to regulate the socioemotional system and because of the differences in maturation of these systems, Steinberg's theory matches well with the age-crime curve of adolescent offending. Consistent with both developmental theories, the Pathways to Desistance Study (a large longitudinal study of serious adolescent offenders) found that 91% of serious adolescent offenders had significant decreases in offending behaviors over 3 years.

Deficits observed in these developmental theories are also observed in psychiatric disorders characterized by antisocial behavior patterns, such as oppositional defiant disorder and conduct disorder (CD). Oppositional defiant disorder is characterized by a pattern of defiant behaviors and angry or irritable mood that results in significant distress in multiple settings (e.g., family, school, peers). CD is marked by a pattern of behavior that violates the rights of others or age-appropriate societal norms or rules. Because these disorders are categorized by the violation of rules, the rates in justice-involved populations are significantly higher than in the general population. Antisocial personality disorder (APD) is marked by an *enduring* pattern of disregard for the rights of others and violation of these rights or of societal norms. Although APD specifies that the pattern of behavior must have been present before age 15 years, personality disorders are not diagnosed until adulthood based on the presumption that personality is variable until this time.

A diagnosis of APD is sometimes conceptualized as a graduated diagnosis from CD. This pattern of

diagnosing CD in adolescence and then APD in adulthood if the pattern of antisocial behavior persists is in line with Moffitt's theory of LCP offending. Again, although prevalence of APD in the general population is low (between 0.2% and 3.3%), prevalence rates of APD in justice-involved populations are estimated at greater than 70%.

RNR Model

A challenge for many clinicians and juvenile justice professionals is how to predict those juveniles who will either reoffend or continue offending into adulthood. When examining how antisocial behavior in adolescence can be predicted, it is important to consider risk and needs factors. Risk factors are mostly stable variables that predict negative outcomes or cause negative outcomes. Conversely, needs factors are conceptualized as changeable risk factors that can be addressed through programmatic interventions or individualized treatments (e.g., impulsivity, thinking patterns).

The Central Eight risk factors are a hierarchical structure of majority dynamic (i.e., changeable) risk factors for recidivism in adult populations. They include what researchers call the *Big Four*—history of antisocial behavior, antisocial personality pattern, antisocial cognition (i.e., antisocial thought patterns), and antisocial associates—and the *Moderate Four*—family/marital circumstances, school/work, leisure/recreation, and substance abuse. The Big Four of the Central Eight are thought to strongly predict recidivism, whereas the Moderate Four are thought to provide incremental validity in the prediction of recidivism. The Central Eight are typically addressed through the RNR model of offender treatment. The RNR model states that offenders should be evaluated and treated based on their individual risk and needs factors as well as on their responsivity to treatment.

Although the Central Eight have been well researched in adult populations, the incorporation of the specific Central Eight is less widespread in juvenile justice research or practice. Nonetheless, the use of RNR assessment measures and treatment models have proliferated in juvenile justice populations. However, these RNR assessment methods typically utilize the Central Eight risk factors without calling them such or without taking into account risk factors potentially unique to

adolescents. For example, risk factors for juvenile justice populations typically categorize individual, family, educational/employment, and peer factors, which easily map onto the Central Eight factors. Other common risk factors frequently discussed among juvenile offenders include history of early aggression, age at first adjudication, and number of prior arrests (i.e., history of antisocial behavior); juvenile psychopathy (i.e., antisocial personality pattern); and antisocial beliefs and attitudes (i.e., antisocial cognitions). The RNR model has been captured in juvenile risk assessments such as the Structured Assessment of Violent Risk in Youth and the Youth Level of Service/Case Management Inventory, and responsivity decisions are often incorporated into mitigating circumstances and sentencing options in juvenile courts.

Final Thoughts

Understanding of juvenile delinquency and antisocial behavior is rapidly increasing at a time when rehabilitation is being emphasized in the juvenile justice system. Insights from cognitive neuroscience and developmental psychology have been incorporated into theories of delinquency and have directly impacted numerous court decisions involving juveniles. This continued evolution holds promise for improving risk prediction, personalizing psychosocial interventions, and informing public policy.

JUVENILE DELINQUENTS, CALLOUS UNEMOTIONAL TRAITS OF

Callous unemotional (CU) traits is the term used to describe individuals showing a set of symptoms including low levels of empathy and guilt, uncaring attitudes about others' feelings and their own performance in structured activities, and shallow emotions. When they co-occur with antisocial behavior, CU traits are recognized to be a risk factor for early onset, pervasive, and aggressive criminal behavior and adult psychopathy. Psychopathy consists of two dimensions or factors: Factor 1 includes shallow and deficient affect and an arrogant and manipulative interpersonal style; Factor 2 includes an impulsive and irresponsible lifestyle and antisocial behavior. CU traits were first introduced to capture developmentally appropriate symptoms of the

deficient affect dimension of adult psychopathy (i.e., lack of remorse/guilt, shallow affect, callous/lack of empathy). Research shows that the presence of CU traits in childhood and adolescence predicts higher instances of aggression—both for personal gain (proactive) and in retaliation for real or perceived wrongdoing (reactive), and antisocial, delinquent, and criminal behavior, in comparison to antisocial youth with no CU traits who tend to show only reactive aggression. This entry focuses on a number of current methods for assessing CU traits and their correlates among juvenile adolescents but is not comprehensive in scope.

Identifying youth with and without CU traits who are on different developmental trajectories to antisocial, delinquent, and criminal behavior is useful for understanding the distinct causal factors involved. Specifically, youth with CU traits show low emotional reactivity to fear- and empathy-evoking stimuli, as well as low anxiety levels, which may underlie their antisocial and aggressive behaviors. Antisocial youth with high levels of CU traits less accurately recognize sad and fearful expressions, are less engaged by others' distress cues, startle less easily when viewing aversive images, and exhibit lower autonomic activity (e.g., heart rate) than those without CU traits. High CU scorers have shown less heart rate change from baseline while viewing emotionally evocative clips as well as reduced brain activation (i.e., in the amygdala) while processing fearful expressions, compared to youth with low CU scores. Theory suggests that this decreased arousal in youth with CU traits prevents the inhibition of antisocial behaviors, explaining chronic patterns of aggressive and violent behavior. These findings support the need for comprehensive and informed assessments of CU traits among antisocial youth to discern those at greatest risk of chronic aggression and violent delinquency and in need of individualized interventions that target their unique needs.

Assessment of CU Traits

In 2003, Adelle Forth and colleagues developed a youth version of Robert Hare's Psychopathy Checklist-Revised, titled the Psychopathy Checklist: Youth Version (PCL:YV). This professional

judgment tool with semistandardized administration procedures provides a dimensional assessment of psychopathic traits among institutionalized adolescents aged 12–18 years. It involves a 60- to 90-min, semi-structured interview supplemented with an extensive file review. Scored on a 3-point scale (0 = *item does not apply*; 1 = *item applies somewhat*; 2 = *item definitely applies*), PCL measures include descriptions for 20 psychopathic traits grouped into affective, interpersonal, and behavioral symptom sets. The PCL:YV differs from the Psychopathy Checklist–Revised by only a few minor modifications for developmental appropriateness reflecting adolescent experiences such as the greater influence of family and peers on adolescents' lives. However, the shallow affect dimension that most closely resembles CU traits can span developmental stages, manifesting similarly in both adolescents and adults.

Adolescents who scored high on the PCL:YV affective dimension showed greater symptoms of disruptive behavior disorders, developed poorer interpersonal relations, and displayed more proactive aggression than their low-scoring counterparts. Meta-analytic studies show that PCL:YV scores moderately predict general (Effect Size r , $ESr = .25$, $p < .001$) and violent reoffending (Effect Size r , $ESr = .21$, $p < .001$). PCL:YV total scores have demonstrated high inter-rater reliability (i.e., the level of agreement between raters; $r = .90$ to $.96$) and internal consistency (α for total = $.83$; interpersonal = $.90$; affective = $.86$; impulsive-behavioral = $.90$) across populations (i.e., institutional, probation, community) within research settings.

PCL measures are resource- and time-intensive to administer (up to 2–3 hr per individual) and require file information, rendering them impractical in many settings. Thus, self-report and informant rating inventories, with a 10- to 20-min completion time, were developed for examining CU traits in broader populations of youth. Meta-analytic studies demonstrate that self-report instruments significantly predict general ($ESr = .11$, $p < .001$) and violent ($ESr = .19$, $p < .001$) recidivism, although effects are somewhat weaker than for PCL measures.

The Antisocial Process Screening Device (APSD), developed by Paul Frick and Robert Hare in 2001, is a 20-item informant (e.g., parent/

caregiver, teacher) or youth self-reporting rating scale designed to measure CU traits, narcissism, and impulsive dimensions of psychopathy in children and adolescents. Items were adapted from the PCL to be more applicable to children and are phrased as statements requiring informants to rate the presence of traits on a 3-point scale (0 = *not at all true*; 1 = *sometimes true*; 2 = *definitely true*). Like the PCL:YV, APSD scores should not be used to make categorical diagnoses of psychopathy, as these traits exist along a continuum.

Children and adolescents scoring high on the APSD/APSD–Self-Report tend to be more aggressive and violent than low-scoring youth. Adolescent offenders with a history of multiple, proactive violent acts scored higher on the APSD than other violent offenders, demonstrating that this tool designates a serious type of juvenile offender with a high frequency of violent acts. APSD total ($r = .33$ to $.40$) and subscale (CU = $.24$ to $.36$; impulsivity = $.32$ to $.40$) scores were significantly correlated with rearrest over a 1-year period. While factor scores for the informant-only version have demonstrated marginal-to-good internal consistency (α for total score = $.85$; CU = $.70$; narcissism = $.76$; impulsivity = $.67$), the internal consistency of scores on the self-report version has ranged from acceptable to good ($\alpha = .72$ to $.82$) for the total score, with poor-to-adequate internal consistency for the subscales (α for CU = $.36$ to $.56$; narcissism = $.56$ to $.72$; impulsivity = $.44$ to $.60$).

After extensive development, Frick produced in 2004 the Inventory of Callous-Unemotional Traits (ICU), a 24-item questionnaire administered to offender and nonoffender samples to help provide a comprehensive assessment of the presence of CU traits. The ICU addresses some of the limitations of the APSD such as the small number of primarily negatively worded items assessing CU traits ($n = 6$). There are five versions of the inventory: parent- and teacher-rating versions for school-age children, parent and teacher versions for preschool children, and a self-report version for school-age children, adolescents, and young adults. A brief 12-item version of the parent/teacher-report ICU has also been developed. Youth with high ICU scores showed more frequent and varied conduct problems, greater

offense histories, and proactive and reactive aggression, compared to low-scoring youth. Incarcerated boys scoring high on the ICU were faster to reoffend postrelease both nonviolently and violently. ICU scores show adequate test–retest reliability and acceptable internal consistency ($\alpha = .77$ to $.89$) across a wide range of ages, sexes, types of samples (community and incarcerated), cultures, and different language translations.

The ICU and the CU Scales of the APSD were used to develop the 4-item symptom criteria set for the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* “with limited prosocial emotions” specifier to conduct disorder. Results of item response theory studies indicated that this 4-item criteria set (i.e., lack of remorse/guilt, callous lack of empathy, unconcerned about performance, and deficient affect) represented the construct of CU traits well, supporting its inclusion in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*. Using a stringent method of assessing CU symptoms from the ICU (i.e., taking only the most extreme responses on the scale) identified community adolescents who were highly antisocial, whereas a more lenient method (i.e., taking the higher two responses of four response options) best distinguished incarcerated antisocial youth.

Recommendations for Use

Accumulating research on the reliability and validity of CU/psychopathy measures provides support for the use of various assessments to examine risk of violence among youth; however, some important considerations are worth mentioning. First, it is well-documented among community and clinical samples of youth that the combination of CU traits and antisocial behavior is a stronger predictor of severe and violent behavior than either factor alone. Yet, the methods used to measure CU tend to focus solely on personality traits rather than including measures of antisocial behavior. This exclusion inevitably limits the utility of CU measures alone for the purposes of violence risk assessment. Second, as with any assessment of mental health in youth, using only self-report to assess CU traits can be problematic and examinees should rely on a multi-informant,

multimethod approach consistent with that used in best practice assessment of childhood behavioral and emotional disorders and as recommended for the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* with limited prosocial emotions specifier. Third, most CU assessments lack normative female samples as girls and women are less likely than male samples to show CU and psychopathic traits, necessitating further research into whether CU traits manifest similarly across sex. Fourth, youth CU/psychopathy assessments are not diagnostic tools. No instrument reviewed here has established cutoff scores for making categorical decisions about whether an individual is a psychopath.

One important issue is that because psychopathy is a personality disorder, there needs to be evidence of relatively stable scores over time and into adulthood. To date, such research is scant, with one notable long-term, follow-up study by Donald Lynam and colleagues measuring psychopathic traits at age 13 and again at age 24, which demonstrated moderate stability of score levels. Although only a minority (16%) of individuals who scored in the top 20% at age 13 went on to attain an adult diagnosis of psychopathy, and the vast majority (84%) did not, the 11-year correlation in this study indicates higher stability for CU traits than for other youth disorders. However, results also suggest considerable within-person variability in psychopathic traits across development.

The CU/psychopathy measures discussed in this entry can assist clinical and forensic professionals in assessing the presence of CU traits among children and adolescents; a construct resembling the deficient affect dimension of psychopathic personality disorder. CU traits appear to best distinguish, among other psychopathy dimensions, those youth on a particularly persistent path of aggressive, violent, antisocial, and criminal behavior. Antisocial youth with CU traits also benefit less from traditional interventions than their low CU counterparts and require targeted interventions that address their unique needs. To illustrate, Michael Caldwell and colleagues found that juvenile offenders scoring high on the PCL: YV were 2.7 times less likely to recidivate following institutional release when

they received a targeted treatment within a specialized juvenile treatment center that utilized reward-oriented approaches, taught empathy skills, and targeted youth's self-interests, relative to psychopathic youth receiving treatment as usual (i.e., services provided by standard juvenile corrections institutions that rely on a punitive approach to deter misbehavior). With enhanced methods of identifying those at greatest risk of aggressive and antisocial behavior, examiners will be better able to allocate resources and administer individualized interventions.

JUVENILE DELINQUENTS, MENTAL HEALTH NEEDS OF

A significant number of justice-involved youth experience mental health disorders, including those related to trauma. Some youth are only mildly affected by their symptoms, and others experience major difficulties in day-to-day living. Not only do incarcerated youth have a constitutional right to mental health treatment but also effective treatment could help curb the high risk of suicide among this population, reduce their emotional/psychological suffering, and help them better utilize programs focused on reducing recidivism. Providing these services effectively, however, is one of the biggest challenges faced by facilities housing delinquent youth. Funding challenges, underqualified mental health professionals, and a more punitive culture can all make effective mental health assessment and treatment less likely. Furthermore, diagnoses and subsequent treatments tend to focus primarily on behaviors, rather than on *why* a youth is behaving a certain way. This is especially troubling with regard to youth dealing with the effects of one or more traumatic incidents who often are not provided trauma-based assessments or treatments. Ideally, justice-involved youth with mental health needs are assessed and provided with evidence-based treatments while residing in the community. If such youth must be placed in a juvenile justice facility, much can be done to reduce their emotional/psychological suffering and harm to self or others as well as increase the positive changes they can make in their own lives.

Mental Health Disorders Among Justice-Involved Youth

Studies have found that 63–92% of youth in juvenile justice facilities meet criteria for a mental health disorder (e.g., attention-deficit/hyperactivity disorder, conduct disorder, post-traumatic stress disorder [PTSD], bipolar disorder, depression) or a substance use disorder. *Co-occurring disorders* (presence of both a mental health and substance use disorder) are common in this population, increasing the complexity of youth assessment, treatment, and management needs.

Regardless of diagnosis, many justice-involved youth experience attention and concentration difficulties, mood swings, low intellectual functioning, irritability, aggression, self-injury/cutting, and suicidal behavior. Participation in outpatient mental health therapy is common, and close to one fifth has been hospitalized in inpatient mental health facilities, with some youth requiring multiple hospitalizations.

Although research on suicide among incarcerated youth is significantly lacking, we know that suicide is the leading cause of death among youth in juvenile justice facilities. One study found that one in 10 youth in juvenile detention thought about killing themselves in the previous 6 months, and a little over one in 10 had attempted suicide at some point in their lives, with many trying to kill themselves more than once. Fewer than half of the youth with suicidal thoughts told anyone about them. Many justice involved youth possess multiple suicide risk factors; those in custody have additional stressors and restricted access to typical coping skills.

Trauma Is the Rule, Not the Exception

Many justice involved youth have been exposed to serious, sometimes life-threatening trauma during childhood and adolescence. One study found that 93% of incarcerated youth had at least one traumatic incident; over half had experienced trauma 6 or more times. Interpersonal traumas such as abuse, neglect, witnessing domestic violence, and separation from parents are common and tend to have the most negative impact. These youth may have angry outbursts, feel numb inside, have a hard time with attention/concentration, and experience interpersonal difficulties. Polytraumatized youth (i.e., single child experiences multiple forms of trauma, often including multiple incidents by multiple individuals) are at double the risk of developing depression, 3 times more likely to develop PTSD, and 3–5 times more likely to abuse alcohol or other drugs. They are also at higher risk of delinquency, school struggles, running away, and suicide.

Studies of incarcerated youth find rates of PTSD ranging from 10% to 50%, with the majority having a substance use disorder and/or another mental health disorder *in addition* to PTSD. The

term *complex trauma* can be helpful for youth who have experienced several (sometimes many) traumatic events, with at least some of the traumatic incidents being interpersonal in nature (e.g., involving family members, trusted individuals, or adults they depend on in some way). With regard to complex trauma, the traumatic experiences typically begin during the younger years and can significantly affect how a child develops, views relationships, and interacts with others. Experiencing repeated and inescapable trauma can impact youths' brain development, resulting in them having more difficulty controlling their emotions, paying attention and learning in school, managing their behavior, and interacting appropriately with peers and/or adults. The way youth view themselves can also be greatly impacted after experiencing a multitude of traumatic events during the developmental years. Not surprisingly, youth with complex trauma are at higher risk of depression, anxiety, substance use, self-injury, and suicide.

Despite high rates of traumatic experiences, justice-involved youth are often *not* diagnosed with a trauma-related condition nor referred for trauma-related treatment. This is usually because symptoms of trauma are often misdiagnosed as another mental health disorder, or the repeated use of alcohol or drugs to cope with traumatic experiences may be solely diagnosed as a substance use disorder—and these then become the focus of treatment. Justice-involved boys tend to underreport physical and sexual abuse as well as suffering related to traumatic experiences, so they may not receive a trauma-related diagnosis. Plus, trauma responses and reactions are often expressed as anger, irritability, and aggression among justice involved youth, which frequently leads to both girls and boys being viewed as *bad* rather than *traumatized*.

When faced with threatening situations, the human brain releases certain chemicals as it goes into fight-or-flight mode. When these chemical responses in the brain are continually reactivated due to chronic trauma, it can lead to structural, molecular, and functional changes in the brain. For youth, these negative changes are associated with significant academic, social, and behavioral problems.

Some practices within the juvenile justice system can exacerbate youths' feelings of vulnerability and loss of control, which can trigger an automatic, biologically programmed fight-or-flight survival response in traumatized youth. This may manifest in oppositional, belligerent, aggressive, avoidant, or self-destructive behavior. When juvenile justice professionals respond with intense punishment or control, physical restraint, or some form of isolation, it may trigger and escalate traumatized youths' negative behavior even further—which typically leads to longer and/or harsher sanctions. As this cycle continues, positive outcomes are less likely and both youth and those who work with them are at increased risk of injury.

Some juvenile justice agencies are moving toward becoming *trauma-responsive*, meaning recognizing the impact of trauma on youth in their care; modifying policies and practices to support youth and help them heal; and integrating the impact of trauma into screening and assessment, case conceptualizations of youth, individualized treatment plans, interventions, and daily programming. Practices that may produce unnecessary stress or inadvertently retraumatize youth are avoided whenever possible. Some examples include not using shackles during courtroom proceedings, allowing multiple opportunities for youth and their parents/caregivers to have a voice in the decision-making process, and reducing (or attempting to eliminate) the use of isolation within juvenile justice facilities. In trauma-responsive care, adults do not ask the question “what’s wrong with you?” but instead focus on “what happened to you?”

Mental Health Screening and Assessment

Mental health *screening* is a brief procedure primarily used to detect youth with a mental health disorder who are in need of further evaluation. Youth identified as possibly having mental health symptoms receive a more extensive assessment to explore the nature and severity of the symptoms to help determine whether specialized treatment services are needed. Upon entry, youth in a juvenile justice program or facility should be screened for possible mental health symptoms; rescreening should occur if youth move to a new residential

placement, display dramatic changes in behavior, or are suspected of developing new mental health issues. Mental health *assessments* can take hours to complete, with results providing the foundation for treatment planning within a program or facility and as youth prepare for transition back to the community. In addition to going more in-depth on issues covered in mental health screening, clinicians assess youths' psychological, intellectual, emotional, and social functioning to better understand areas of challenge and success.

Justice involved youth are often over-, under-, and misdiagnosed with mental health disorders. Mental health diagnoses should only be assigned after a comprehensive and thorough assessment by clinicians who have the education, training, and experience to do so.

Youth from various racial and ethnic backgrounds can manifest mental health symptoms differently; some mental health instruments have been developed for middle-class White males, so results may not be valid when assessing youth of other races, backgrounds, or another gender. The Massachusetts Youth Screening Instrument—Version 2 is a mental health screening tool normed on justice-involved youth; however, most mental health instruments are not.

Screening and assessment is an ongoing process. Youth may be intoxicated when initially screened; serious mental health disorders may develop or increase in severity as youth move into late adolescence; and a youth's depressed mood, anxiety, or suicidal thoughts may disappear after a major stressor is removed.

Mental Health Treatment

Youth with mental health disorders, including those with head injuries and trauma-related brain changes, typically need interventions focused on thinking before acting, managing their anger, decreasing or discontinuing substance use, developing prosocial coping skills, reducing stress, decreasing trauma-triggered responses, correctly perceiving social cues, and empathizing with others.

The following treatment models have shown beneficial effects for justice-involved youth; however, research has primarily been done in the community: Cognitive Behavioral Therapy and Trauma-Focused Cognitive Behavioral Therapy,

Multisystemic Therapy, Multidimensional Treatment Foster Care, Dialectical Behavior Therapy, Motivational Interviewing, Functional Family Therapy, and Trauma Affect Regulation: Guide for Education and Therapy. Research on effective treatment methods for incarcerated youth with mental health needs (especially those who are aggressive and violent) is limited and desperately needed.

Home-based, family-oriented psychotherapy that is individualized to a youth and family's needs is typically more effective for low-risk youth and those charged with nonviolent offenses (e.g., non-violent probation violation) versus detaining or incarcerating them. Following release from a juvenile justice facility, this type of treatment can help reduce a youth's mental health symptoms, lessen family conflict, and decrease the likelihood of youth requiring residential treatment or returning to a juvenile justice facility.

Diversion programs are often available to help keep youth with mental health disorders out of the juvenile justice system, particularly if they have committed minor offenses and/or are not a threat to public safety. Youth who are diverted typically need to complete several requirements, including evidence-based individual and family treatment in the community. If diversion out of the juvenile justice system is not possible, youth should be placed in the least restrictive, most homelike setting that is safely possible and provided evidence-based treatment where they reside.

Justice involved youth with serious mental health disorders may require intensive intervention services or residential placements, including: intensive home-based treatment, therapeutic foster care, day treatment program, and/or an inpatient psychiatric hospital or residential treatment program. Parents or caregivers may need crisis intervention services or access to respite care.

Juvenile justice facilities vary considerably in physical design, quantity and quality of mental health resources, and provision of mental health treatment and programming. Goals of mental health treatment for incarcerated youth typically include stabilizing emotions and behavior, decreasing violence toward themselves and others, maintaining safe facilities and orderly living units, and reducing youth suffering and impairment in key areas (e.g., family, school, friendships). The most

helpful treatment strategies teach youth effective skills to better control their emotions and behavior, as well as necessary skills for functioning successfully in the facility, as well as the community upon release.

Successful treatment typically addresses multiple areas of youths' lives, including family, peers, school, community, and, when necessary, youth's physiology (through medication). Treatment services should be practical, skill-based, focused on developing and strengthening protective factors (vs. solely reducing mental health symptoms), and modified for youths' intellectual and developmental levels. Quality education and vocational programs are essential, as are a variety of recreation and leisure activities, meaningful programs, strength-based behavior management, and positive relationships with peers and adults. Youth are more likely to attend and participate in mental health services in lieu of, or after, release from a juvenile justice facility if services are mandated by probation or parole.

Key Treatment Issues

Specialized mental health courts have been developed in some jurisdictions across the United States to help meet the needs of justice-involved youth. They are voluntary, less adversarial than typical courts and ensure youth receive appropriate mental health assessments and treatment. A multidisciplinary team develops and monitors youths' treatment plans; utilization of existing community resources is emphasized; and juvenile detention is used as a last resort.

Not all clinicians assessing and treating justice-involved youth with mental health disorders have the education, training, and experience to work with this challenging and clinically complicated population. Many have not been trained on how to provide mental health assessments or evidence-based mental health treatment or they may not be well-versed in working with adolescents, particularly those who may be oppositional, angry, or even aggressive. In some juvenile justice programs and facilities, there are limited resources to fund one or more qualified mental health professionals or it may be challenging to attract qualified individuals who want to work with justice-involved youth. Utilizing unlicensed

or underqualified mental health professionals reduces the likelihood that justice-involved youth will receive the type and quality of treatment services they need. Juvenile justice facilities, especially in rural areas, may need to be creative and flexible (e.g., obtaining grant money to fund the positions, building relationships with community mental health centers, utilizing traveling mental health professionals who visit different facilities throughout the week, sharing mental health professionals with the local jail) in order to attract and retain qualified mental health professionals.

Engaging parents and caregivers in the assessment and treatment process, including educating them on the benefits and risks of each treatment option, is essential for positive outcomes. Informed consent is typically required if youth are prescribed medication to treat mental health symptoms.

Prior to or during justice involvement, many youth have been prescribed psychotropic medication to help control their moods or behaviors. For some, this medication is vital to their success (even lifesaving); however, the benefit and safety profiles of many of these medications are largely unknown for young people. Psychotropic medication is particularly complicated and potentially dangerous among justice-involved youth for several reasons: They often do not take psychotropic medication as prescribed, they may take several different types of medication simultaneously, and they frequently use alcohol/drugs at the same time.

If incarcerated youth with mental health disorders are not adequately prepared for the transition back to the community, they can become overwhelmed, frustrated, and discouraged. To prevent a loss in treatment gains, support and services from multiple systems (e.g., family, mental health, substance abuse, school/vocational, housing, child welfare, medical) should be in place upon release; family involvement is essential.

Given the high numbers of justice-involved youth with mental health disorders, mental health training (with an emphasis on trauma) is needed for all juvenile justice professionals. Working with this population can be stressful, and juvenile justice professionals who receive little or no mental health training can easily become frustrated and discouraged, leading to burnout and ineffective—and sometimes harmful—management and supervision strategies. Without training on how to effectively

interact with this group of young people, staff can unintentionally escalate a crisis situation, exacerbate youth distress, or trigger a deterioration of youth mental health symptoms.

Neither the juvenile justice system nor mental health system can effectively manage and treat justice-involved youth with mental health disorders single-handedly. Communication, coordination, and collaboration are necessary among and between mental health and justice system professionals, parents/caregivers, and the youth themselves. Ideally, interdisciplinary collaboration should begin as soon as a youth enters the juvenile justice system and continues throughout all mental health assessment, treatment, and transition services.

JUVENILE OFFENDERS

The term *juvenile offenders*, or *juvenile delinquents*, refers, generally, to youth who commit a legal infraction; however, there are variations across jurisdictions in statutory age limits and the offenses considered legal infractions. Statutory ages defining a juvenile offender generally range between 12 and 18 years. In some jurisdictions,

though, youth as young as 6 years can be charged with a criminal offense. Similarly, in some jurisdictions, depending on the crime, a youth under the statutory age limit can be charged as an adult. Types of infractions meriting charging a youth as a criminal offender vary as well. In some cases, status offenses such as truancy or running away are considered criminal acts, whereas in other jurisdictions these are treated outside the juvenile justice system.

To further understand juvenile offenders, this entry begins with a discussion of the evolution of contemporary conceptions of childhood. It then discusses theories and factors associated with juvenile offending as well as implications for prediction, prevention, and treatment. The entry concludes with a discussion of various juvenile justice systems.

Contemporary Conceptions of Childhood

Current attitudes and practices regarding youth who engage in criminal activity have evolved over a long period of time. This evolutionary process has roughly paralleled the evolution of attitudes and practices regarding childhood and adolescence. Historians have traced a slow and uneven development of the concept of childhood and ideas about the appropriate treatment of youth. Earlier periods were characterized generally by the absence of a concept of childhood. Childhood was treated simply as a preparation for adulthood; as soon as youth reached some early milestones (e.g., puberty), they were considered part of the adult world. For example, youth as young as 12 years were recruited into the navy, and children as young as 8 years were taken to work in the coal mines. To an extent, this may have been a class and gender issue, but even males from the upper classes were not provided the same type of childhood experienced today.

The evolution of contemporary conceptions of childhood as a distinct phase of the life span emerged slowly during the early 19th and 20th centuries. Much of this evolution was sparked by philosophic and political developments associated with the Enlightenment, social issues arising from increasing urbanization, and developments in religious thought. This shift is also reflected in society's attitudes and practices regarding juvenile

offenders, whereby they are usually (although not always) provided separate treatment in the judicial system.

Analyzing the construct of juvenile offending is complicated by a number of considerations, such as the nature of the offense and pattern of offending. Most crimes committed by youth are relatively minor in nature, including actions such as shoplifting, damaging property, and engaging in minor fights. At the other end of this continuum are acts of serious violence such as murder and sexual assault. Frequency of offending is also relevant. In many cases, the youth offender has committed a single infraction, while in other cases chronic offending is present.

A related distinction is between adolescent-limited and life course–persistent delinquency. The former describes much juvenile crime, whereby a youth with no criminal history engages in some form of law breaking during adolescence. Usually, these crimes are not particularly serious and the youth does not persist in criminal activity. Life course–persistent delinquency, on the other hand, describes the pattern whereby antisocial behavior and conduct disorder appear very early and persist through adolescence and into adulthood. While these two patterns do not describe all patterns exhibited by youth, they do account for a high percentage of cases.

That the construct of juvenile offending can include youth exhibiting a wide range of patterns of criminal activity complicates analyses of the causes of delinquency as well as prediction and treatment strategies. These issues also complicate evaluations of the extent of juvenile crime. Data regarding the incidence of youth crime and percentage of youth engaging in criminal activity are often reported. Sometimes these data are traced over time, indicating, for example, that youth crime has increased or decreased in a particular region over some period of time. Comparisons are sometimes made among jurisdictions as well. However, these data are difficult to interpret because of the ambiguities regarding definitions of the construct just discussed. For example, calculating the percentage of youth in a community convicted for a crime does not convey necessarily specific information as this number may include youth exhibiting a range of infractions (from shoplifting to murder) as well as a range of patterns (from a youth convicted of one

offense to a youth with a long history of convictions). Moreover, deficiencies are sometimes present as well in the data on which these comparisons are based, including those derived from official sources.

In spite of these problems, some conclusions related to juvenile offending can be stated with confidence. First, the majority of youth do not engage in serious criminal activity or, at any rate, serious enough to come to the attention of the police. Second, a small number of youth do commit criminal acts serious enough for police and judicial involvement; however, the majority of these crimes are relatively minor, and the youth do not engage in continued criminal activity beyond adolescence. Finally, a very small number of youth engage in serious criminal activity, and in some cases, the criminal activity is chronic. The latter requires close attention in order to effectively predict and prevent juvenile offenders and devise appropriate treatment strategies.

Theory

Theoretical efforts to analyze the causes of juvenile offending have a long history. However, two complications should be noted at the outset. First, analyzing the causes of a complex human behavior such as criminal activity, subject as it is to a wide range of influences, is immensely complicated. Second, as already mentioned, the construct itself is complicated. Is it possible that a single cause can explain the actions of a youth with no criminal history engaging in the theft of a bicycle as well as a youth with a long criminal history engaging in a violent assault? Nevertheless, many have attempted to develop theories related to juvenile delinquency as a whole.

From these studies, four broad categories of theories for juvenile offending can be identified. Neoclassical theories emphasize rational choice as the basis for the criminal offending. Criminal behavior is viewed as willful; people engage in the criminal act because they choose to. A second category implicates biological processes. In some cases, deficits in neurological functioning are hypothesized, while in other cases genetically based determinants of temperament are implicated. Psychological explanations form a third category. This category actually includes a variety of explanatory

constructs, ranging from psychoanalytic processes, through social learning, to purely behavioral explanations. Finally, economic or sociological theories locate the causes of criminal behaviors in social or economic contexts. Marxist and anomie theories, for example, posit that criminal activities reflect responses to poverty and economic inequality.

While theories within each of the four categories contribute to the understanding of crime, it is recognized that none alone provides a complete explanation. For this reason, some contemporary scholars have eschewed a purely theoretical analysis and depend on research-based conclusions regarding the factors associated with youth crime. This also has the advantage of providing specific guidance regarding prediction and treatment strategies.

Factors Associated With Juvenile Crime

Considerable progress has been made through empirical research in identifying individual and situational factors associated with youth crime. Some of these factors or conditions are causal in nature. For example, associations with delinquent peers in a gang may contribute directly to the criminal act. In other cases, the factor may reflect a statistical association and indirect link with the criminal activity. For example, while poor school performance is associated with crime, this may reflect frequent absences associated with the criminal activity or may reflect differential treatment of the child in school because he or she has been identified as delinquent.

Whether or not a condition is causal, identifying the condition as significantly associated with criminal activity is important from the point of view of identifying a youth as at risk for criminal activity and for focusing intervention efforts. The presence of a risk factor does not mean that the youth will necessarily commit a delinquent act, but it indicates an increased probability relative to youth not exhibiting the condition. For example, a youth involved in a criminal gang may not engage in criminal activities, but he or she has a higher likelihood to do so than a youth not so engaged.

Scholars have identified eight categories of major risk factors. The first category includes historical factors, such as a history of conduct disorder and criminal activity. Other things being equal, a youth

with a history of antisocial behavior is at elevated risk of crime. A second category includes a range of family factors, particularly those relating to parenting. A lack of supervision, inappropriate disciplinary practices, and poor relations between parent and youth are prominent risk factors. Poor school adjustment and achievement have also been linked with youthful criminal activity, as has association with antisocial peers. Drug and alcohol addiction, poor use of leisure time, and a range of personality and behavioral traits (e.g., attention disorders, high levels of hostility and aggression, callous/unemotional perspective) have also been linked with antisocial behaviors. Finally, antisocial attitudes, values, and beliefs have demonstrated strong relations with youthful criminal acts. Again, the presence of these factors or conditions does not necessarily mean the youth will engage in criminal behaviors; rather, it increases the probability this will occur. Research also indicates that the greater the number of risk factors exhibited by a youth, the higher the probability of committing a criminal act.

A distinction is made between static and dynamic risk factors. The former are conditions that cannot be changed. These include historical factors such as age at first arrest and a history of criminal activity. Dynamic risk factors (also referred to as needs) constitute risk conditions that can be changed and, if changed, can reduce the likelihood of engaging in criminal activity. Most of the factors or conditions identified in this entry represent dynamic risk factors. While not easy, positive changes can be made in all of the areas except for the historical factors. Parental practices can be improved, youth moved away from negative peer influences, school performance and adjustment improved, drug and alcohol abuse addressed, improvements made in use of leisure time, personality and behavioral problems addressed, and attitudes and values moved in positive directions. Research has demonstrated that positive changes in these areas can reduce the likelihood of engaging in criminal activities.

The discussion to this point has focused on negative traits or conditions associated with criminal activity. However, it is also important to recognize that the youth, or his or her environment, may present strength or protective factors that could help to buffer or counter the effects of the negative factors. An example would be a cooperative and resourceful parent who may serve as a buffer to

negative neighborhood influences or a teacher willing to work with the youth on school problems. Characteristics of the youth may play important roles in fostering strength or protective factors: a high level of maturity in the youth, an interest in sports, or a recognition that changes in his or her life may create a positive impact. Identifying strength or protective factors is particularly important for developing effective interventions; thus, to the extent possible, intervention or treatment efforts should be strength based.

Implications for Identification and Prediction

Identifying youth at risk of criminal offending or continued offending is an important exercise since it can guide prevention and treatment strategies. In the present context, this involves identifying risk and need factors for the youth and using those as the basis for predictions about engaging in criminal acts.

A purely clinical approach is sometimes used for identification and prediction. A professional, possibly a probation or youth worker, with experience in the field interviews the youth, reviews any additional information about the youth, and forms judgments, including predictions about the risk of further criminal activity. However, research has shown that clinical assessments of this type are generally not particularly reliable or valid. That research has also shown that structured and standardized assessment procedures yield more valid predictions of future behavior. The preferred approach to forming profiles of risk or needs and predictions of risk of delinquency is based on the use of structured and standardized assessment instruments, such as the Structured Assessment of Violence Risk in Youth and Youth Level of Service/Case Management Inventory 2.0.

Implications for Prevention and Treatment

A common assumption among some professionals, politicians, and members of the public is that punitive sanctions, particularly in the form of incarceration, represent the most effective means for promoting individual and general deterrence. The argument is that the experience of such a

sanction or knowledge of the threat of a negative sanction will deter engaging in the criminal activity. However, contemporary research has shown that punitive sanctions are not particularly effective in promoting deterrence. In fact, under some circumstances subjecting a youth to coercive sanctions may actually increase the probability of reoffending. This same program evaluation research also suggests that rehabilitative strategies focusing on the factors placing the youth at risk of criminal activity can be the most effective intervention strategy. This does not mean that the youth should not be held accountable for a transgression, but it does shift the focus from the criminal act to the youth committing the act.

A number of intervention models have been developed to guide this type of strategy. One such framework, the Risk-Need-Responsivity (RNR) model, has received empirical support and is used here as an example of best practice in the treatment of the juvenile offender. This model asserts that careful assessments of the risk and need factors exhibited by the youth (*assessment principle*) help with determining effective interventions. According to the *risk principle* of the RNR model, the level or intensity of treatment should vary with the level of risk presented by the youth. In other words, intensive interventions should be reserved for the highest risk cases, while lower risk cases can be provided less intensive interventions. Intensive interventions for all at-risk youth would be cost prohibitive, so correlating risk and intervention levels offers a practical approach. Also, research has shown that involvement in the judicial or correctional systems can, under some circumstances, represent a risk factor. Disposition of a youth's case will always involve judicial considerations (e.g., based on severity of the offense or history of offending), but within those limits, system involvement with the youth should reflect the level of risk presented.

The second principle of the RNR is the *need principle*, which states that interventions should be directed toward the specific needs of a particular youth. If, for example, a youth exhibits risks related to the home environment, associations with delinquent peers, and drug abuse, then these should be the targets of service. On the other hand, if the risks appear to be associated primarily with adjustment problems in school, poor use of

leisure time, and antisocial attitudes, then those can be the objects of intervention.

A third principle of the RNR model, the *responsivity principle*, suggests that interventions should take into account other factors or conditions that may affect responses to the intervention. This includes negative factors such as conflicts between parents, cultural issues, emotional conditions of the youth, as well as strengths exhibited by the youth or family. Responsivity factors are not necessarily directly related to the criminal activity, but they should be identified in assessments and taken into account in case planning. Other principles within the RNR model stress the use of valid assessment procedures, the use of evidence-based treatments, the use of community-based interventions where possible, and the careful selection and training of personnel within the judicial or correctional system.

A growing body of empirical research is now providing support for the principles of the RNR model. Additionally, research is showing that systems following the principles of the RNR model present favorable cost/benefit ratios compared with alternatives, particularly those dependent on more punitive approaches such as incarceration. The latter tends to be very expensive and relatively ineffective in deterring criminal activity.

Systems of Juvenile Justice

Juvenile justice systems include police, courts, and correctional subsystems. The latter may comprise community-based intervention programs designed to deter criminal activity, probation services, and custody or other institutional facilities. Sanctions such as fines or community service orders may also be involved. The design of these systems varies widely across national boundaries and even within countries in some cases. For example, while the processing of youth within the courts in the United States is directed to some extent by higher court decisions, the legal processing of juveniles and the range of sanctions employed differs from state to state. The situation in Canada is somewhat different. Legal processing of juveniles and approved sanctions is under the control of the Youth Criminal Justice Act, an act of the federal parliament. However, the application of the act is

a provincial responsibility and some variability in application is observed among the provinces.

Differences among systems can be represented in terms of two dimensions, one relating to legal procedures and protections and the other to preferred sanctions. At one extreme are crime control systems in which the focus is on the crime rather than the offender. Here, the youth is processed through a formal legal system, with a heavy dependence on punitive sanctions such as incarceration. In extreme cases in this type of system, the youth may be accorded no legal rights, with the court holding all decision powers. These systems sometimes reflect a *parens patriae* philosophy, whereby the court is acting in the best interest of the child.

The other extreme is reflected in child welfare systems where the primary focus is on rehabilitating the youth rather than punishing the crime. Here, the youth is not exposed to a formal legal system but is processed through a social welfare or child protection system with the primary focus being rehabilitation instead of punishment.

Many juvenile justice systems fall somewhere between these two extremes. Many possess a separate court system for youth that contains most of the due process protections of the adult system. Although nearly all have a provision for punitive sanctions, many systems also incorporate some rehabilitative treatment programs. However, there are wide differences in the balance of punitive and rehabilitative strategies, particularly across the United States. Wide differences across jurisdictions are also observed in attempts to incorporate principles of best practice as represented in models such as RNR.

While the treatment of juvenile offenders is directed very much by political forces, it is hoped that continuing research on the effectiveness of various strategies for addressing youth crime will contribute to improvements in the future. Efforts to educate the public on the importance of using best practices in the treatment of juvenile offenders are also important.

JUVENILE OFFENDERS: DEVELOPMENTAL TREATMENT CONSIDERATIONS

Adolescence is a tumultuous time of profound development across neurocognitive, social, biological, self/identity, and moral domains. Some degree of rule breaking, conflict with authority (e.g., parental, school), and antisocial behavior (e.g., curfew violations) is considered normative during adolescence. However, for adolescents with juvenile justice involvement, the neurobiological, social, and identity-formation tasks of this developmental period may at least partially contribute to the onset and course of delinquent behavior. Therefore, it is imperative that treatment providers who assess and treat youthful offenders target dynamic, changeable risk factors such as antisocial behavior, which may stem from the developmental changes that take place during adolescence, to provide the best opportunity for reducing the likelihood of further antisocial behavior.

Adolescent Brain

The development of the adolescent brain has been the subject of much study and debate in reference to juvenile justice. This is a rich and complex area of research, but two neurobiological systems are generally acknowledged as particularly relevant to adolescent behavioral control and offending behavior: the cognitive control system, which is responsible for executive functioning, and the

socioemotional system, which is responsible for the processing and integration of interpersonal and affective stimuli. Although both the cognitive control system and socioemotional system develop substantially during adolescence, they do not mature at the same rate.

The socioemotional system matures quickly following puberty and is typically considered to be fully developed between the ages of 15 and 16 years. This system refers to brain structures and functions that allow for the processing and integration of relational and emotional stimuli. Included neural structures include the amygdala, orbitofrontal cortex, insula, medial prefrontal cortex, ventral striatum, and superior temporal sulcus (see Figure 1). The socioemotional system is also closely associated with the brain's reward pathways that are responsible for the motivation to seek pleasurable experiences and avoid

unpleasant ones. The rapid development of the socioemotional system may also help explain the intense affective states and lability (or rapidly changing emotional states) that are often observed during adolescence.

In contrast to the socioemotional system, the cognitive control system continues to mature throughout adolescence and into early adulthood, with some areas of the prefrontal cortex not reaching full maturity until between the ages of 20 and 25 years. Skills associated with the cognitive control system include those required to assess a situation, weigh potential response options, develop a plan of action, and act accordingly. Underdeveloped executive functioning skills are associated with deficits in mental flexibility, planning, attention, and the integration of feedback.

The observed pattern of impulsivity and risk-taking that is often present in adolescence may be

Figure 1 Brain areas that participate in social processing. A simple classification of brain areas involved in social processing differentiates regions that participate in four related processes. The first is the perception of basic social stimuli, such as biological motions (V5), part of the body (extrastriate body area, EBA), and faces (fusiform face area, FFA). Another process includes emotional and motivational appraisal, where the amygdala (AMY), the anterior insula (AI), the subgenual and perigenual anterior cingulate cortex (ACC), and the orbitofrontal cortex (OFC) participate. These cortical structures are in interaction with subcortical structures as the ventral striatum (VS) and the hypothalamus (HTH). These structures in turn interact with other regions that participate in the goal-directed, adaptive behaviors and the categorization processes, such as the dorsolateral and the medial prefrontal cortex (dlPFC, mPFC) and the ACC. Finally, for social attribution, areas such as the ventral premotor cortex (vPMC), the superior temporal sulcus (STS), the AI, the posterior cingulate cortex (PCC), and the precuneus (PC) participate in more automatic, bottom-up inferences of other people's mental states, whereas structures such as the medial prefrontal cortex and the temporoparietal junction (TPJ) are involved in more cognitive theory of mind skills.

Source: Wikimedia Commons/Billeke, P., & Aboitiz, F. (2013). Social cognition in schizophrenia: From social stimuli processing to social engagement. *Frontiers in Psychiatry*, 4(4). doi:10.3389/fpsy.2013.00004. Retrieved from <http://journal.frontiersin.org/article/10.3389/fpsy.2013.00004/ful>. Licensed under Creative Commons Attribution 3.0 Unported, <https://creativecommons.org/licenses/by/3.0/deed.en>

the result of the temporal lag between the maturation of the social–emotional processing system of the brain and that of the cognitive control system. Specifically, the absence of fully developed skills related to executive control (i.e., an underdeveloped cognitive control system) coupled with a strong orientation toward pleasurable and social influences (flowing from a fully developed socio-emotional system) can lead to deficits in judgment, planning, and decision-making, particularly in the context of highly socially or emotionally salient situations. These executive functioning deficits (relative to mature adults) and strong social–emotional impulses, which are hallmarks of adolescence, are associated with juvenile offending behavior. By contrast, among nonoffending adolescents, there is more congruence in the development of the emotional processing system and the cognitive control system, meaning that both systems tend to develop at approximately the same time.

Social Development and the Influence of Peers

Adolescence is a critical period of social development, and the active pursuit of peer approval and acceptance is a normative component of this development. Therefore, peer influence, including negative influence, is a particularly powerful factor during this developmental stage. Generally, the influence of peers manifests as two related processes: social comparison, which involves evaluating one's own behavior by observing the behavior of others, and social conformity, which is the tendency to emulate the behavior of certain peers. Social conformity is of particular importance to adolescent development because the tendency to conform behavior to match that of peers peaks in mid-adolescence (around 14 or 15 years of age) and then slowly declines during late adolescence.

Peer influence is related to juvenile-offending behavior in several important ways. First, perceived peer rejection during adolescence often results in increased risk-taking behavior in an effort to gain acceptance from peers. As such, youth who perceive themselves to be socially awkward, incompetent, marginalized, or excluded may be particularly vulnerable to involvement with the juvenile justice system. Second, in

comparison to adults, adolescents tend to commit more group-based offenses. This provides further support for the social (rather than individual) motivation for offending behavior often observed among juveniles. Third, antisocial peer influence is a powerful risk factor for antisocial behavior among adolescents, which suggests that treatment providers working with youthful offenders should assess and address antisocial peer contact. Fourth, the normative developmental need for affiliation may be particularly problematic for adolescents immersed in subcultures (e.g., gangs) where the so-called delinquent reputations are promoted as desirable. This highlights the importance of gang prevention efforts for at-risk youth in areas where gang activity is prevalent. Finally, the offending behaviors of adolescents who become involved in the juvenile justice system for a time but do not go on to exhibit persistent offending behavior into adulthood—referred to as *adolescence-limited antisocial behavior*—are frequently motivated by a desire to imitate antisocial peers who occupy a higher social status.

In light of the research related to social-peer influence during adolescence, the behavior of many juvenile offenders can be distinguished from that of typical adult offenders. In particular, adults who engage in offending behavior are more likely to behave in accordance with a subjectively defined personal value system, whereas adolescent-offending behavior is much more likely to be shaped by the developmentally appropriate (albeit sometimes problematic) social forces that are present during this stage of development.

Biological Development/Puberty

In addition to the substantial neurodevelopmental and social changes typical of adolescence, juveniles undergo significant physiological changes during puberty. This development is accompanied by hormonal fluctuations, including increases in testosterone in males and estradiol in females. The hormonal changes of puberty are strongly associated with aggression and irritability in both sexes. Adjusting to physical manifestations of puberty can be a stressful experience for adolescents, and it impacts how youth think, feel, and behave. Accordingly, personality functioning is often less stable (i.e., less consistent across contexts) before

and during puberty than it is during adulthood. Further, biological development may impact juvenile-offending behavior by increasing irritability and aggression.

Identity Development

Identity formation is the key developmental task of adolescence, and it is a process by which individuals strive to identify their personal, ethnic, gender, sexual, and social identity. The pursuit of a sense of self is commonly accompanied by a conflict between two opposing concepts: the need for independence and individuation versus the need for affiliation and social connectedness. This struggle can lead to behavioral difficulties and represents a challenge for adolescents. The development of maladaptive coping strategies, such as substance use, in response to identity-related struggles is closely linked to delinquent behaviors among youth.

The process of identity formation is typically characterized by extensive experimentation and exploration during the course of adolescence. Although this identity crisis typically occurs during middle adolescence, its resolution and the subsequent assimilation of personally relevant identity elements into a cohesive *developed self* does not typically occur until late adolescence or early adulthood. Often the experimentation process inherent to identity formation includes risk-taking behaviors such as substance use, sexual experimentation, and antisocial behavior. Stunted identity development, including when adolescents have difficulty exploring or committing to personal value systems, is associated with a variety of negative outcomes, including poor self-confidence, low levels of intrinsic motivation, younger age at first arrest, and higher rates of arrest.

Psychosocial Maturity

Forensic mental health professionals are commonly asked to opine about concepts such as *sophistication* and *maturity* in the context of juvenile forensic mental health evaluations. A consideration of a juvenile's sophistication and maturity may be relevant, for example, when forensic mental health professionals are assisting courts to determine whether a juvenile should be processed

in juvenile court or adult court. The constructs of sophistication and maturity are closely linked with the psychological concept of *psychosocial maturity*, which is the process of individual decision-making that is affected by a number of cognitive, emotional, and social factors. There are three functional capacities that contribute to the concept of psychosocial maturity: (1) *responsibility* (the ability to make independent decisions and remain relatively self-reliant in the face of external pressures); (2) *perspective* (the ability to identify and weigh short-term and long-term consequences of a decision [temporal perspective] and the ability to identify and understand another individual's position on an issue [interpersonal perspective]); and (3) *temperance* (the capacity to exhibit self-control and restrain impulses).

Typically developing juveniles tend to exhibit responsibility by late adolescence. Both temporal and interpersonal perspectives tend to improve throughout adolescence, so younger juveniles (i.e., aged 10–14 years) exhibit immature perspective-taking when compared to older adolescents (i.e., aged 16 and 17 years). When perspective is underdeveloped, adolescents tend to display poor judgment, in part because they assign greater value to short-term rather than long-term consequences. The discounting of longer-term consequences is a risk factor for adolescent-offending behavior. Youth tend to exhibit stable levels of temperance from childhood to approximately 16 years of age. Around age 16, impulsivity increases and temperance decreases for several years, until approximately 19 years of age. Thus, older adolescents can be expected to display less developed temperance than younger children in the context of juvenile forensic assessment and treatment.

Treatment Considerations

There are numerous internal and external factors that influence adolescent development. As part of the normative developmental process, adolescents experience significant and profound changes in several domains, including neurological, social, physiological, psychological, and emotional. The accompanying neurobiological and identity formation developmental tasks associated with adolescence are likely related to the observed patterns

of rule-breaking behavior, conflict with authority, and antisocial behavior seen in some adolescents.

From a treatment perspective, treatment providers working with juvenile offenders should be knowledgeable about the normative developmental changes that take place during adolescence. Understanding these processes is essential in the assessment process and when formulating an appropriate treatment plan. By understanding the normative process of adolescent development, treatment providers can better distinguish youth likely to desist offending behavior (i.e., adolescent limited) from the smaller portion of adolescents who are likely to continue engaging in antisocial behavior in adulthood (i.e., life course persistent).

JUVENILE OFFENDERS: TREATMENT MODELS AND APPROACHES

Treatment models and approaches for juvenile offenders consist of a variety of theories and applications that aim to reduce juvenile delinquency. Within the general subject of criminal psychology, this topic concerns policies and services to both promote prosocial youthful development (e.g., regular school attendance, participation in structured activities) and rectify the antisocial circumstances (e.g., substance abuse) and manifestations of youths who become involved in the juvenile justice or criminal justice systems. The topic is relevant to professionals working within and outside of the formal juvenile justice system, including clinicians, educators, caseworkers, probation officers, attorneys, judges, and policy makers. Treatment models and approaches can be organized in terms of where they are positioned along the juvenile justice or criminal justice processing continuums, by the *name brand* of the service, by the generic principles or elements that make up the service, or by the subtype of juvenile offenders being targeted. At the present time, there is also much interest in evidence-based treatments, in particular, and how to appropriately and effectively balance punitive and rehabilitative responses to juvenile offending.

A System-Processing View

Primary or universal prevention programs aim to reduce the number of justice-involved youth, and the likelihood of status offenses (i.e., behaviors that are only offenses because of the youth's juvenile status; e.g., curfew violations) or delinquent offenses is to adopt policies (e.g., repeal of zero-tolerance laws, promotion of increased inter-agency and interorganizational collaboration among such entities as schools, child health-care providers, child welfare agencies, and community-outreach organizations) and provide services (e.g.,

home visitation programs that provide assistance with health care, infant care, and child development; public information campaigns; gang-focused initiatives) to prevent contact with the justice system. *Secondary or selective prevention* approaches attempt to *divert* youth who make contact with the juvenile justice system. School officials, police officers, juvenile court intake officers, prosecutors, and juvenile court judges can offer school-based discipline, informal warnings, referral for acute mental health or substance abuse services, or dismissals of juvenile court referrals and petitions. Youth participation in teen, peer, or drug courts is also included in the secondary or selective prevention approach.

Another approach to reducing the numbers of justice-involved youth—*treatment*, or *intervention*, *tertiary prevention*, and *aftercare*—is to provide community- or institution-based services to youths adjudicated of status or delinquent offenses in the juvenile court system or convicted of criminal offenses if processed in adult court. Community-based treatment options are numerous and include home-based supervision, case management, and treatment via probation or parole with house detention, electronic monitoring, or day reporting; mediation or victim reconciliation; restitution and community service; alternative education; job training and placement services; day treatment; substance use treatment; counseling; mentoring; family support services; independent living services; and reentry and aftercare (after incarceration) services. They also include out-of-home, but noninstitutional or postinstitutional placements, such as foster homes and specialized foster care programs, group homes and halfway houses, hybrid family-group homes, shelter-care programs, and residential wilderness or outdoor adventure programs. Juvenile correctional facilities can be categorized in different ways, including public versus private institutions, secure-closed versus open facilities, and preadjudicatory or detention (e.g., detention centers, adult jails) versus postadjudicatory or confinement facilities (e.g., diagnostic and reception centers; ranches, forestry camps, farms, and outdoor programs; boot camps; closed-environment state training schools and more open cottage institutions; and inpatient substance misuse and mental health facilities). The services provided in these institutions are diverse

and include behaviorally oriented milieus and token economies (i.e., a method of behavioral management based on rewarding positive behavior); educational and vocational training programs; physical–nutritional and mental health care; individual, group, family, and religious counseling; substance misuse treatment; sex offending treatment; and leisure and recreation programs.

Name-Brand Services

Listings of model-exemplary programs that have withstood rigorous empirical evaluation and replication (and less-supported but still promising programs) are available from the Blueprints for Healthy Youth Development database, the National Registry of Evidence-based Programs and Practices, the Office of Juvenile Justice and Delinquency Prevention Model Programs Guide, and CrimeSolutions.gov, all of which describe U.S.-based model programs. Only eight evidence-based programs have passed the demanding inclusion criteria for designation as a model program in the Blueprints for Healthy Youth Development database. Of these, most environmentally oriented model programs focus on changing the home environment: Nurse-Family Partnership (home visits and early childhood education), parent management training (parent training), Functional Family Therapy (family therapy), and multisystemic therapy (family therapy). Although the central aspect of these four approaches may be attention to the family unit, environmentally focused programs like Functional Family Therapy and multisystemic therapy intervene across a youth's social ecology, at the level of the individual youth and his or her family, peers, school, and community, to address person- and social-level risk factors for antisocial behavior. One other environmentally focused model program—Positive Action—focuses on changing the school environment through the establishment of behavioral norms or expectations. The remaining model programs focus on the individual. Three involve social skills training, behavioral strategies, and cognitive behavioral techniques: LifeSkills Training, Project Towards No Drug Abuse, and Promoting Alternative Thinking Strategies. The other individual-oriented model program—Treatment Foster Care Oregon—involves community supervision and aftercare.

Although not included in the Blueprints for Healthy Youth Development database, it has been suggested that Aggression Replacement Training, an individual-focused intervention involving training in social skills, emotional control, and moral reasoning, has accrued sufficient empirical support to be classified as an exemplary program.

Generic Service Principles or Elements

In recent years, meta-analysis (empirically aggregating findings across studies) has served as the primary technique for appraising the effectiveness of different treatment models and approaches for juvenile offenders. Based on these methods, there is reliable evidence that juvenile treatment programs have, on average, a modest but meaningful effect on recidivism, and, moreover, that name-brand and generic programs can be more or less effective than one another. What seems to be more important than whether a program is a well-known model approach is the match of the program with juvenile offenders' criminogenic needs (i.e., risk factors for delinquency capable of change via intervention), the characteristics of the program, and the fidelity of the program delivery. Identified principles of effective prevention, court intervention, and correctional treatment for juvenile offenders include the following:

- primary service
- supplementary service (adding another service component tends to increase effectiveness; together with primary service type, accounts for 40% of positive effects)
- treatment amount (sufficient per the indicators of service frequency, program duration, and program quality; accounts for 25% of positive effects)
- risk level (programs are generally more effective with high-risk than low-risk juvenile offenders, and concerns about high-risk juvenile offenders having a negative influence on low-risk juvenile offenders appear related to unstructured time rather than time spent together in professionally run programming; accounts for 20% of positive effects)
- treatment quality (quality of implementation and delivery influence effectiveness; accounts for 15% of positive effects)

The elements of juvenile court programs associated with the smallest to largest positive effects are (in order from smallest to largest effects) (a) average supervision program, (b) above average effectiveness service, (c) above average effectiveness service and a best supplement service, (d) the two preceding plus an optimal service amount, and (e) the three preceding plus appropriate participants.

Above average effects can be observed for youth who have not been processed within the juvenile justice system but are placed in prevention programs that address interpersonal skills, parent training or counseling, and tutoring or remedial education; average effects are observed for drug and alcohol therapy or counseling and employment or job training; and below average but still positive effects are observed for individual counseling, family counseling, and mentoring.

Meta-analysis has also allowed for the ranking of various treatment types, with counseling seeing the strongest effects, followed by skill building (e.g., cognitive thinking skills, social skills, academic skills, vocational skills), multiple services (e.g., case management, service brokerage arrangements), restorative justice (e.g., community service or restitution, victim-offender mediation), and surveillance (e.g., intensive probation or parole supervision).

Within the counseling modality, effective approaches are rank-ordered from strongest to least strong: group, mentoring, mixed, family, family crisis, mixed with referrals, individual, and peer. Within the skill-building domain, the rank ordering of effective approaches from strongest to least strong is cognitive behavioral, behavioral, social skills, academic, and vocational.

Services for Specific Types of Juvenile Offenders

Owing to the effectiveness of intensive, individualized, multidimensional home- and community-based programs, interventions for juvenile sex offenders should advance beyond the traditional model of cognitive behavioral group therapy that focuses on sexual attitudes and beliefs, emotional knowledge and affect regulation (i.e., controlling emotions), and relationship building. Consistent with this suggestion, a program for juvenile sex offenders that has been designated as a model prevention program

by the Blueprints for Healthy Youth Development project is a variant of Multisystemic Therapy for Problem Sexual Behavior. Such approaches also hold promise for, or have demonstrated effectiveness with, other subtypes of juvenile offenders, such as very young juvenile offenders, high-risk juvenile offenders, and status offenders. For example, both multisystemic therapy and parent and teacher training approaches have demonstrated some success with status offenders. Other promising prevention approaches for status offenders include school truancy programs (e.g., career academies, schools within schools, graduated responses; i.e., the use of increasingly strong rewards and punishments) and multiservice diversion programs. There is also some evidence that programs used with boys are also effective for girls, whether they are treated separate from or alongside boys. However, more research is needed on gender-specific programming.

Meta-analysis can aid in determining programs and the extent of their effectiveness for juveniles already processed within the juvenile justice system, specifically probationers and confined juvenile offenders. For juvenile probationers, above average effects are observed with cognitive behavior therapy, group counseling, mentoring, vocational training, some drug abuse treatment, and some sex offender treatment; average effects are observed with individual counseling, family counseling or therapy, integrated multimodal services, remedial education or tutoring, life skills training, some drug abuse treatment, and some sex offender treatment; and below average but still positive effects are observed with recreation, restitution, challenge programs, intensive supervision, some drug abuse treatment, and some sex offender treatment. For confined juvenile offenders, above average effects are observed with behavior management, cognitive behavior therapy, interpersonal skills training, and employment or job training; average effects are observed with individual counseling, group counseling, and family counseling; and below average but still positive effects are observed with tutoring or remedial education, and career or vocational counseling.

Meta-analysis has also been used to determine the direction and reliability of effects achieved by different approaches for noninstitutionalized versus confined serious and violent juvenile offenders, respectively. For nonconfined serious and violent juvenile offenders, consistently positive

effects are observed with behavioral programs, individual counseling, and interpersonal skills training; less consistently positive effects are observed with multiple services and restitution with probation or parole; inconsistent and mixed, but generally positive effects are observed with family counseling, group counseling, advocacy or casework, academic programs, and employment-related services; inconsistently weak or no effects are observed with reduced probation or parole caseloads; and consistently weak or no effects are observed with deterrence programs, wilderness challenge programs, vocational programs, and early release from probation or parole.

For confined serious and violent juvenile offenders, consistently positive effects are observed with interpersonal skills and teaching family homes; less consistently positive effects are observed with behavioral programs, community residential programs, and multiple services; inconsistent and mixed, but generally positive effects are observed with individual counseling, group counseling, and guided group counseling; inconsistently weak or no effects are observed with employment-related services, drug abstinence programs, and wilderness challenge programs; and consistently weak or no effects are observed with milieu therapy.

In summary, contemporary prevention and intervention models for juvenile offenders adopt a developmentally informed, social-ecological, risk-needs perspective on juvenile delinquency and attend also to noncriminogenic (i.e., factors not related to the propensity to reoffend) mental health and welfare needs. They also propose how to reconcile calls for juvenile offenders to be held accountable for their behavior, to the extent that punitive responses are reasonable and appropriate. Treatment approaches can be classified as prevention, diversion, or intervention policies or services depending on the stage at which they are offered as a youth is processed through the social services, juvenile justice, or criminal justice systems. In addition, exemplary treatment approaches are often known by name, although services can be classified and evaluated according to generic principles or elements that make up the treatment approach. Furthermore, tailored treatment models and approaches exist for subtypes of juvenile offenders. The appeal of evidence-based services (including cost-effectiveness) and advocacy on behalf of

scientifically informed, comprehensive, coordinated, humane, and just responses to the problem of youth crime, are likely to drive continued advancements in treatment models and approaches for juvenile offenders in the coming years.

JUVENILE SEX OFFENDER RECIDIVISM RISK ASSESSMENT TOOL-II (JSORRAT-II)

The Juvenile Sex Offender Recidivism Risk Assessment Tool-II (JSORRAT-II) was originally developed by Douglas Epperson in collaboration with

the Utah Juvenile Justice Services as an actuarial assessment of risk. Actuarial assessments aim to make risk assessments based on well-established statistical relationships (e.g., weather forecasting relies on statistical models to predict storms but cannot predict with 100% accuracy), as opposed to clinical assessments (e.g., making a judgment of risk based on information gained from the psychosocial interview). The JSORRAT-II was designed to evaluate the risk of sexual recidivism for male sex offenders whose sexual offenses occurred between the ages of 12 and 18 years. The tool provides an overall score (ranging from 0 to 21) that is comprised of scores on 12 static, or unchanging, variables: number of adjudications for sexual offenses, number of victims, the time span of the documented sexual offending, presence of court-ordered supervision while offense occurred, offense occurred in a public place, presence of grooming or deception, treatment history, physical abuse history, sexual abuse history, special education placement, discipline problems during education time periods, and adjudications for nonsexual offenses. The tool, if used properly, can provide a fairly reliable measure of sexual recidivism risk, although it is currently only validated for use in Utah, Iowa, California, and Georgia.

Scoring

A number of items on the assessment are scored as either 0 or 1, signifying the absence or presence of risk factors, respectively (e.g., presence of court-ordered supervision while offense was committed, offense committed in a public place). Other items indicate a range of scores from 0 to 2 or 0 to 3 to denote a level of severity for specific risk factors (e.g., number of different victims is scored as 0 for one victim, 1 for two victims, or 2 for three or more victims). Individuals who receive an overall score of 8 of 21 or higher are placed at a moderate-to-high risk of recidivism, those who receive a score of 4–7 are deemed at moderate risk, scores of 1–3 classify an individual at a low-to-moderate risk, and those with a score of 0 are viewed as low risk.

Prior to completing the assessment, it is crucial that evaluators review the entire file and only include information contained within the file. The assessment requires data from the offender's officially adjudicated offense case file; uncharged

offense information should not be included in the scoring of items. This is due to the fact that the items that were found to contribute to the predictive validity of the assessment were developed by using only officially adjudicated offense information, and thus, predictive validity is maintained when users follow the same standard. When information provided in the case file is insufficient, evaluators are instructed to make an estimate when possible. If the information in the file is deemed insufficient to make an estimate, the item should be coded as *U* (unable to score). Further, if the item is not relevant to the individual, it should be coded as *NA*. The unambiguous and objective nature of the items, along with the detailed scoring instructions, potentially allows for high reliability.

Psychometrics

Research has evaluated the basic psychometric properties of the JSORRAT-II including its validity and reliability as a risk assessment measure. It was originally developed through examination of possible predictor variables from a large sample of juvenile sex offenders in Utah. Statistical analyses were then utilized to identify pertinent variables most predictive of juvenile sexual recidivism. Overall, evaluations of the accuracy of the JSORRAT-II demonstrate that its effectiveness as a predictor of recidivism prior to age 18 significantly exceeds chance (Area Under the Curve, $AUC = 0.89$, $d = 1.74$). The JSORRAT-II was also subjected to cross-validation using another sample in Utah (Area Under the Curve, $AUC = 0.65$, $d = 0.53$) as well as a sample in Iowa (Area Under the Curve, $AUC = 0.65$, $d = 0.54$). Additionally, it has demonstrated high inter-rater reliability across users ($ICC = 0.96$ in one study and 0.89 in another). While the JSORRAT-II has demonstrated predictive utility and adequate psychometric properties, no actuarial assessments are 100% accurate; thus, the tool should be used in the context of a larger assessment procedure.

It should also be noted that in one study, when validated on a sample totally independent from which it was originally developed, the JSORRAT-II did not accurately predict sexual reoffending. Interestingly, it has also been found that the JSORRAT-II did not achieve the same levels of predictive accuracy for juveniles who had offended exclusively against their siblings ($ROC = 0.58$;

95% CI from 0.43 to 0.73), which may prompt clinicians to use caution when interpreting results with this population.

Since the initial study of the JSORRAT-II's accuracy, subsequent psychometric studies have revealed a decrease in the predictive accuracy of the assessment tool. Researchers have found that this diminished level of accuracy for the tool cannot be explained by missing data, severity of the index sexual offense, or age at risk assessment. However, it is still unclear exactly why the predictive accuracy decreased from the initial validation study compared to the subsequent studies.

Critiques

Despite the decreased accuracy over time with repeated validation studies, a strength of the JSORRAT-II is that it utilizes an actuarial approach to prediction. Given the many heuristical errors that can erode the accuracy of clinical predictions, it follows that actuarial prediction has generally been found to have increased accuracy compared to clinical prediction. However, this is not to say that any actuarial measure is satisfactory—its actual quality depends on the demonstrated accuracy of measurement, which in turn can only be interpreted in the context of what sort of *accuracy* is sought in the particular prediction task. For instance, a highly accurate prediction of cancer is more important than a highly accurate prediction of acne, and false negatives are more troublesome than false positives in cancer predictions, as providing treatment to someone who does not need it is less harmful than not treating someone with the disease. However, the examination of the rates and types of errors that are acceptable in the context of sex offending prediction have been insufficient. Further, as noted earlier, this instrument has significant limits on its predictive validity. There has been too little evaluation of the kinds and amounts of error that are acceptable in the context of sex offending predictions.

It is also important to note that many of the other psychometric properties (e.g. discriminate validity), as well as the degree to which the instrument generalizes beyond the validation sample, remain unknown. Specifically, it is unclear if this instrument can be used with special populations, such as those who are developmentally delayed, non-English speakers, females, and members of

minority groups. Clearly, there is a need for more studies evaluating the psychometric properties, particularly with diverse samples. Further, the JSORRAT-II is primarily used in conjunction with other measures including record reviews, other diagnostic testing, and clinical interviews. These additional assessments are important as they allow for a more inclusive consideration of dynamic factors. However, this is also problematic as those utilizing the JSORRAT-II are instructed to solely rely on the information contained in the file, and violating this may disrupt the instrument's predictive utility. A final issue to consider regards the *broken leg problem*—in which a dynamic factor (e.g., a recent broken leg) disrupts a well-established statistical relationship (e.g., playing basketball every Friday). Currently, there is a need for researchers to investigate how information from the JSORRAT-II ought to be synthesized with such additional dynamic information to produce more accurate conclusions (i.e., incremental validity).

Competitors

In addition to the JSORRAT-II, two of the other most widely used risk assessments for the prediction of juvenile sexual offenses are the Juvenile Sex Offender Risk Assessment Protocol-II (J-SOAP-II) and the Estimate of Risk of Adolescent Sexual Offense Recidivism (ERASOR). All three scales differ in several important ways, including their intended purpose, development, structure, and length. Additionally, moderators such as age and type of offense committed impact the validity of each scale. For instance, the J-SOAP-II and the ERASOR have been found to have higher levels of predictive validity for juveniles who have committed only sexual offenses compared to those who also had a history of non-sexual offending.

The J-SOAP-II is the most widely employed risk assessment tool and is designed to predict risk of sexual violence and general delinquency for adolescent males aged 12–18 years with a history of sexual aggression. The scale is composed of a 28-item checklist of risk factors that are clinically relevant and empirically supported. Items on the scale are scored on a three-point system, and like the JSORRAT-II, higher scores indicate increased

risk of recidivism. Despite its wide use, the J-SOAP-II has no classification related to the various scores, and thus this scale is not an actuarial assessment but rather functions as an *empirically informed guide*.

The ERASOR is composed of 25 items and was created based on structured professional judgments. Evaluators make their own judgments of low, moderate, or high risk based on the items, as well as other factors, such as the psychosocial interview, not included in the file that may be relevant. The ERASOR, like the J-SOAP-II, distinguishes between static or immutable risk factors and dynamic or contextual risk factors. While the ERASOR and J-SOAP-II consider contextual information, both fail to provide actuarial assessments. The JSORRAT-II, on the other hand, provides a brief actuarial measure but is not always attuned to other relevant information. Overall, the JSORRAT-II has some evidence that it provides a fairly accurate risk estimate for juvenile sex offenders, although its predictive validity has been strongest in samples from which it was validated, prompting its use only within a larger assessment context.

JUVENILE SEX OFFENDER RISK ASSESSMENT PROTOCOL-II (J-SOAP-II)

The J-SOAP-II is a structured risk assessment tool designed to evaluate risk of sexual violence and general offending in adolescent males (12–18 years) with a history of coercive sexual behavior. The J-SOAP-II is relevant to the field of criminal psychology given that it is one of the most commonly administered risk assessment tools designed for adolescent sexual offenders in the United States and Canada. Moreover, the J-SOAP-II was specifically designed to aid in treatment planning and in monitoring treatment-related change. After a description of the J-SOAP-II, this entry discusses its purpose and development and provides a brief overview of empirical findings regarding its reliability and validity.

Description and Purpose of the J-SOAP-II

The J-SOAP-II comprises a 28-item checklist designed to assess and manage risk of sexual violence and general delinquency and can be administered as part of a comprehensive assessment. The 28 items form four distinct scales, two of which are viewed as static or historical (i.e., Sexual Drive/Preoccupation Scale and Impulsive/Antisocial Scale) while the remaining two are

modifiable or dynamic (i.e., Intervention Scale and Community Stability/Adjustment Scale). All items are operationally defined with behavioral anchors and scored using a three-level rating system (i.e., 0, 1, and 2) with all items weighted equally. Table 1 displays the J-SOAP-II items by scale.

Although initially intended to be an actuarial assessment tool (i.e., a risk assessment tool that provides probabilistic estimates of sexual reoffending based on total scores or predetermined cutoffs), the J-SOAP-II does not provide cutoff scores or probability of risk. Rather, total scores may be calculated by summing the items for the J-SOAP-II and its individual scales. In addition, static and dynamic scores can be calculated by summing Items 1–16 and 17–28, respectively. To further aid in interpretation, the level of risk may be calculated for each score by dividing the summed value by the total possible score for the scale. Adjustments to the scoring criteria or total scores are not recommended; nevertheless, incorporating risk-relevant factors not otherwise reflected in the tool (i.e., case-specific risk/protective factors), and adjusting the adolescent's overall risk accordingly, is permitted on the basis of the clinical opinion of the assessor. Therefore, it is possible that an adolescent may be deemed high risk by an assessor despite scoring low on the J-SOAP-II (and vice versa). Moreover, should insufficient information be available for scoring items, assessors are encouraged to rate items favoring lower risk; however, the potential for the underestimation of risk in such instances should be acknowledged.

Because of rapid developmental changes occurring during adolescence, the authors of the J-SOAP-II recommend that regular reassessments occur during the course of treatment and prior to release from custody to monitor change in risk. Such reassessments should occur at a minimum of every 6 months, particularly if any risk-relevant changes occur (e.g., expulsion from school). However, if an adolescent is currently incarcerated in a correctional facility or residential treatment program, it is recommended that the Community Stability/Adjustment Scale not be rated unless the youth resided for a minimum of 2 months within the community prior to incarceration. Likewise, following release from custody, adolescents have to be in the community for

Table I Juvenile Sex Offender Risk Assessment Protocol-II (J-SOAP-II) Items by Scale

Sexual Drive/Preoccupation
1. Prior Legally Charged Sex Offenses
2. Number of Sexual Abuse Victims

25. Management of Anger
26. Stability of Current Living Situation
27. Stability in School
28. Evidence of Positive Support Systems

a minimum of 3 months before the Community Stability/Adjustment Scale items may be scored.

Development of the J-SOAP-II

The J-SOAP-II is a revision of the 1994 tool, the J-SOAP. Initial item selection was based on an

extensive review of the empirical literature on adolescent and adult sexual offenders (e.g., clinical and risk assessment or outcome studies), which resulted in the development of 23 items that are divided into four subscales: Sexual Drive/Sexual Preoccupation; Impulsive, Antisocial Behavior; Clinical/Treatment; and Community Adjustment. In 1998, following an initial validation study, an additional 3 items were incorporated into the tool, and further clarification of item descriptions was provided. In the early 2000s, several studies were conducted to examine the factor structure, reliability, and validity (e.g., concurrent and predictive) of the J-SOAP. These studies informed the next round of revisions to the J-SOAP that would result in the development of the J-SOAP-II.

Based on the study results in the early 2000s, a number of significant changes were made to the items of the J-SOAP. First, several new items were introduced to the Sexual Drive/Preoccupation Scale (i.e., Number of Sexual Abuse Victims, Male Child Victim, Sexualized Aggression, and Sexual Victimization History), while the item High Degree of Sexualizing the Victim was removed and Sexual Drive and Preoccupation (formerly referred to as Evidence of Sexual Preoccupation/Obsessions) was revised. Second, 3 items were removed from the Impulsive/Antisocial Scale: History of Substance Abuse, History of Parental Substance Abuse, and Impulsivity. Furthermore, Physical Assault History/Exposure to Family Violence was added, Caregiver Consistency was revised, and School Suspensions or Expulsions was collapsed into School Behavior Problems to reduce overlap in item content. Third, items within the Intervention Scale were revised to reflect changes in behavior and attitudes related to both sexual and nonsexual offending, while the item Evidence of Empathy, Remorse, and Guilt was divided into 2 items (i.e., Empathy, and Remorse and Guilt). Last, Management of Sexual Urges and Desire was added to the Community Stability/Adjustment Scale, while Quality of Peer Relationships was moved to the Intervention Scale. Overall, these revisions culminated in the development of the 28-item J-SOAP-II in 2003.

Reliability and Validity of the J-SOAP-II

As the J-SOAP-II was designed for use with only male adolescents with a history of coercive sexual

behavior, research investigating its reliability and validity has been conducted with male adolescent sexual offenders. With respect to reliability (i.e., internal consistency and inter-rater reliability), the J-SOAP-II has demonstrated good internal consistency across total and scale scores, and inter-rater agreement has typically ranged from good to excellent, although there is some evidence to suggest that inter-rater agreement is slightly higher at discharge. Moreover, validity measures of the J-SOAP-II have been strong, especially when administered with other adolescent sexual offender risk assessment tools such as the Estimate of Risk of Adolescent Sexual Offense Recidivism and violence risk assessment tools such as the Structured Assessment of Violence Risk in Youth.

While the J-SOAP-II total score has been found to be a moderate (and significant) predictor of sexual and nonsexual reoffending at the aggregate level, variability in predictive accuracy has been observed across the scale scores with the Sex Drive/Preoccupation and Intervention Scales displaying lower predictive accuracy relative to the Impulsive/Antisocial Behavior and Community Stability/Adjustment Scales. Nonsignificant differences at the aggregate level have been found for the J-SOAP-II in predicting sexual and nonsexual offending when compared to other adolescent sexual offender risk assessment tools such as the Estimate of Risk of Adolescent Sexual Offense Recidivism. Furthermore, there is some evidence to suggest that the predictive validity of the J-SOAP-II is moderated by sex offender typology, with higher predictive accuracy for sexual reoffending being observed in youth who have engaged only in sexual offending (i.e., sexual offending without prior delinquent behavior) in comparison to youth who have engaged in sexual and nonsexual offending (i.e., sexual offending with prior delinquent behavior). However, the reverse has been found with higher predictive accuracy for nonsexual reoffending observed among youth with a history of sexual offending with prior delinquent behavior. Lastly, with respect to potential moderators, while comparable predictive validity has been demonstrated for the J-SOAP-II across settings (i.e., correctional vs. residential treatment), preliminary research examining its predictive accuracy among Singaporean male adolescent sexual offenders has demonstrated

somewhat mixed results; however, further research is required in this area as researchers have yet to examine whether cultural factors directly moderate the predictive validity of the J-SOAP-II.

Moreover, research examining change in dynamic risk on the Intervention and Community Stability/Adjustment Scales has been somewhat mixed. For instance, significantly greater reductions in dynamic risk (as a result of treatment) have been observed in youth rated as moderate risk relative to youth rated as high risk. Additionally, statistically significant reductions in dynamic risk factors on the J-SOAP-II have been observed among adolescent sexual offenders who have undergone a residential, cognitive behavioral treatment program. However, despite the magnitude of the change, and that just under half of the youth demonstrated reliable reductions in risk, neither the change scores nor the presence of reliable reductions in dynamic risk on the Intervention and Community Stability/Adjustment Scales is found to be consistently predictive of sexual, violent nonsexual, and general (i.e., any) reoffending. Surprisingly, after statistically controlling for the static scales of the J-SOAP-II, the presence of reliable change on the Community Stability/Adjustment Scale was associated with a significant increase in sexual and general reoffending. In contrast, however, reliable change on the Intervention Scale was associated with a significant decrease in reoffending, though only for sexual reoffending. While such results support the dynamic (i.e., modifiable) nature of the items on the Community Stability/Adjustment and Intervention Scales, further research is required to determine the impact of such changes on offending behavior.

Future Research

The J-SOAP-II is among the most widely used and researched risk assessment tools designed for use with adolescent sexual offenders. Development of the J-SOAP-II has been driven by empirical findings, and there is a growing body of evidence supporting its reliability and validity. Although the dynamic nature of the risk factors incorporated into the J-SOAP-II has been demonstrated, supporting its use for monitoring treatment-related change, further research is needed.

Moreover, due to a lack of research focusing on implementation outcomes and relevance to intervention planning/risk management, future research should examine the factors related to adherence and feasibility of implementing the J-SOAP-II and determine the effectiveness of tailoring risk management strategies based on the dynamic risk factors incorporated in the tool and whether such strategies result in reduced rates of sexual reoffending.

JUVENILE SEX OFFENDERS: ASSESSMENT

According to the most recent estimates by the Office of Juvenile Justice and Delinquency Prevention, there were a total of 1.32 million juvenile arrests in 2012. Of these juveniles, 12,400 were arrested for sex offenses. The largest proportion of perpetrators of juvenile sex offenses reported each year are male (90%) and White (72%) adolescents. Although sex offenders represent a small proportion of offender populations, protecting individuals from sex crimes and providing early interventions for sex offenders have been an ongoing concern among the general public and policy makers.

A growing area of interests within the field of corrections is risk assessment. The goal of risk assessment is to provide correctional practitioners (e.g., probation officers, juvenile court officers) and judges with information concerning an offender's potential risk of committing future crimes. The adoption and use of proper risk assessments for juvenile sex offenders (JSOs) means that correctional practitioners will be informed about rehabilitation needs of JSOs, which in turn may reduce risk of reoffending through adulthood. Research suggests that JSOs are distinct from adult sex offenders. For example, JSOs have fewer victims, engage in less aggressive acts of violence, are less likely to have victims that are strangers, and are more likely to be involved in illegal sexual behavior as the result of curiosity and experimentation. Given that there are potentially different factors that predict sex crimes for adults, it is critical for juvenile courts to use risk assessments that address the unique needs of juveniles who engage in illegal sexual activity.

The Use of Risk Assessments for Juvenile Offenders

The use of risk assessments has a long history in justice system practice that started with the adult justice system. Risk assessments for juvenile offenders are one-way juvenile practitioners who systematically identify the presence and severity of key static (stable over time) and dynamic (changing) criminogenic risk factors that may lead to ongoing delinquent behavior. Examples of static criminogenic risk factors include criminal history, family criminality, and age at first offense, whereas examples of dynamic criminogenic risk factors include peer relationships, education, and involvement in antisocial activities. By examining static and dynamic risk factors using standardized measurements, juvenile courts can not only determine a juvenile's probability of reoffending but also identify specific programs that may reduce criminogenic risk. Further, these tools also provide courts with a system to track a youth's progress based on the services and treatment received.

Static and dynamic risk factors typically fall within one of eight central areas that predict general delinquency (i.e., assault, shoplifting, theft, breaking and entering). These central eight criminogenic risk areas measured by general risk assessments include antisocial behavior (e.g., aggression), antisocial personality (e.g., impulsive/lacks self-control), cognition (e.g., antisocial beliefs), antisocial peers (e.g., delinquent peers), family (e.g., lack of supervision or poor quality relationships with parents), school/work (e.g., problems at school), leisure/recreation (e.g., use of free time), and substance abuse (e.g., alcohol and drug use). While these eight areas have been useful for estimating a juvenile's risk of involvement in general delinquency, some criminologists and psychologists have questioned the utility of these risk areas for predicting future sex offenses. As a result, specific risk assessment tools have been developed to predict sex offenses to capture risk factors uniquely associated with illegal sexual behavior.

Specialized Risk Assessments for JSOs

Past research shows that general risk assessments are effective in determining whether or not non-JSOs or JSOs will be involved in general

delinquency; however, research is both scant and mixed concerning how well general assessments correctly identify juveniles at risk of a future sex offense. Although general risk assessments capture some factors that are relevant to JSOs (e.g., impulsive behaviors and antisocial attitudes), these assessments do not assess characteristics unique to sex offenders (e.g., deviant sexual interests, access to victims, and sexual preoccupation). As a result, general risk assessments fail to gather information necessary to guide treatment plans of JSOs.

Once a JSO is adjudicated/sentenced due to some illegal sexual behavior, a juvenile court officer (i.e., probation officers) and judge must identify which rehabilitation efforts will best benefit JSO. JSO risk assessments have provided decision makers with the opportunity to make standardized recommendations concerning treatment needs and level of services. To identify the risk and needs of a JSO and accurately predict persistence of sex offending, assessors should focus on a juvenile's past and current sexual behaviors, experiences, and belief systems. Commonly measured static risk factors on JSO assessments include history of sexual abuse and victimization, history of sexual violence against others, history of antisocial behavioral problems, and history of sex offender treatment program experiences. Dynamic factors commonly measured by JSO risk assessments include the following: sexual attitudes and deviant sexual interest, poor social connections with others and underdeveloped social skills, low levels of empathy for others, antisocial personality, negative psychosocial functioning, negative family functioning, negative environmental conditions, social isolation, and poor parent-child relationships. Given the link between these aforementioned risk factors and sexual deviance observed among JSOs, these risk factors have been the starting place for many sex offender assessments used by courts today. As more research is conducted in this area, there will be increased opportunities for courts to better understand which static and dynamic factors are most meaningful in the assessment of JSOs.

Commonly Used JSO Risk Assessments

The two most common JSO risk assessments with promising ability to predict a future sex offense and highlight target risk areas critical for reducing

sexual recidivism include the Juvenile Sex Offender Assessment Protocol-II (J-SOAP-II) and the Estimate of Risk of Adolescent Sexual Offense Recidivism (ERASOR). The J-SOAP-II, the most popular JSO assessment, is comprised of 28 items that are divided into four subcategories: sexual drive preoccupation, impulsive/antisocial behaviors, interventions, and community stability/adjustment. The ERASOR includes 25 items that fall within five subcategories: sexual interests, attitudes and behaviors, historical sexual assaults, psychosocial functioning, family/environmental functioning, and treatment. Although there is great overlap between the subcategories of the J-SOAP-II and ERASOR, empirical evidence concerning validity and utility of these measures is mixed.

Research concerning the accuracy and validity of JSO assessments shows some promise in predicting sexual recidivism. In the case of a JSO, the goal of juvenile court probation officers and judges is to determine how well an assessment can predict future crime. The ability for an assessment to perform over and above chance suggest that the standardized measure outperforms *professional decision-making* or a *hunch*. The use of validation studies provides practitioners with information concerning how valid risk assessment tools are in predicting future crime.

One of the largest validation studies on the J-SOAP-II suggests that this instrument has good internal consistency, meaning the measurement items are closely related to the same phenomenon (i.e., sexual recidivism). The J-SOAP-II has also been identified as a measure that has both construct validity (i.e., the extent to which items measure what they claim to measure) and predictive validity (i.e., the extent to which scores predict future behavior) for future sex offenses. Further, one validation study found that the J-SOAP-II total score was also a significant predictor of general recidivism. This means that J-SOAP-II was able to identify those juveniles who had an increased likelihood of coming in contact with the juvenile justice system for general offenders as well as sex offenders about 33% above chance. While the J-SOAP-II shows some promise, some studies found that the J-SOAP-II barely performs as well as chance.

Similarly, research is promising yet mixed with regard to the validity of the ERASOR. Research

studies on the ERASOR also have inconsistent reviews. While some studies indicate that the ERASOR has shown some promise in predicting sexual recidivism (14% above chance), other studies have reported estimating future recidivism as low as 4% above chance. These findings suggest that there is still room for improvement in identifying the factors most relevant to predicting future sex offending among juvenile populations. Given studies concerning the validity of these assessments are limited, increasing research in this area will allow courts to increase their ability to identify risk and intervention needs for JSOs.

Shortcomings of JSO Risk Assessments

One limitation of studies that have tested if JSO risk assessment instruments are valid predictors of future sex crimes is that these studies are conducted on very small samples of juveniles. For instance, current validation studies have examined the predictive validity of sex offender risk assessment among small samples of juveniles of mostly male offenders. In addition to small sample sizes, there is also a low base rate by which sex crimes are committed and reported. Low base rates in occurrence and reporting make it difficult to determine the factors that matter most in predicting future sex crimes. As a result, there is still much to learn concerning the factors that predict sex offending.

Further, of the validation studies that exist, many risk assessment tools are tested with juveniles who have been found guilty by the court and placed in a residential treatment program. This is problematic because excluding community-supervised JSOs who may not share the same characteristics as those in residential facilities may lead to a misunderstanding of risk factors that predict future sex offenses. Given that the initial purpose of risk assessments is to use risk factor information to guide treatment plans prior to placement, more studies are needed that examine all juveniles who are involved in the juvenile court due to a sex offense charge prior to adjudication (i.e., sentencing).

Finally, other studies show variation in predictive validity across demographic characteristics such as gender and age. For example, there is evidence to suggest that these tools are better predictors for

older offenders and male offenders. These observations are likely due to the small number of girls and younger juveniles involved in and/or being reported for a sex crime. While low rates of involvement in sex crimes are good, identifying appropriate measures for JSOs will take more time. For JSO risk assessments to be seen as accurate mechanisms to predict future sex offenses, it is important that these instruments be validated on larger and more diverse populations (e.g., girls, different age groups, residential and nonresidential samples).

Conclusion

In all, while the utility of these assessment tools appears promising, more evidence is needed to say with confidence that these tools should be used in practice for various subpopulations of JSOs (e.g., by gender, race/ethnicity, and incarcerated vs. community supervised JSOs). The policy implications concerning assessing JSOs are vast, and adopting risk assessment practices for decision-making about JSOs should be informed by empirically validated research. If courts adopt JSO assessment tools, they must correctly assess level of risk of recidivism and intervention needs and validate the assessments for their population to ensure accuracy.

The use of risk assessments for JSOs is just one step toward addressing the unique needs of juveniles engaged in illegal sexual behaviors. If courts are able to identify key static and dynamic risk factors that impact JSOs, the likelihood of reoffending, and particularly sex crimes, can be substantially decreased. Further, courts would have the opportunity to create new prevention and intervention programs that may best reduce the likelihood a sex offense would occur by targeting dynamic needs unique to JSO populations.

KNOWLEDGE DESTRUCTION VERSUS KNOWLEDGE CUMULATION

A disturbing trend in the field of corrections has been the appearance of pseudoscientific arguments, otherwise known as *knowledge destruction*, to discount policies affecting the lives of offenders and the protection of the public. This entry begins with a definition of knowledge destruction, traces its philosophical roots, describes its key elements, and then explores examples of how knowledge destruction has generated erroneous conclusions in three areas of corrections research: the prediction and the treatment of criminal behavior and the effects of prison life. Then, the entry closes with an antidote to knowledge destruction by outlining a constructive approach to the cumulation of scientific knowledge and contrasts the results from this approach in the three aforementioned research domains.

Knowledge Destruction

The philosophical roots of knowledge destruction can be traced back to the 17th century. Francis Bacon was of the view that oftentimes people's beliefs were based on their prejudices and the sociopolitical cultural fashions of the day. These beliefs were maintained by selecting only the information that reinforced one's views that were defended by resorting to magical thinking. Bacon claimed that this reasoning led to superstitious beliefs (e.g., astrology, omens).

Subsequently, a school of philosophy arose in the late 18th century that challenged the skepticism of Bacon and others (e.g., Hume). The Scottish philosopher Thomas Reid proposed a commonsense theory, later popularized by James Beattie, which had an appealing innate quality to it. That is, everyman was imbued with commonsense intuitions derived from his or her everyday experiences. These experiences, moreover, were trustworthy and never in error. This method of reasoning had a persuasive appeal as wisdom was now conferred upon all classes of people, rich and poor, the learned and unlearned. One did not need to be a so-called expert to voice an informed opinion on an issue.

The basic elements of commonsense thinking functions have evolved since Reid's time; in the 21st century, scholars have fleshed out the constituents of common sense into three essential components:

1. *Sources of knowledge.* The sources are qualitative based on the authority, intuition, and the morally superior vision of the observer. Furthermore, there is no one truth on a topic that is under investigation since all knowledge is partial, relative, socially constructed, and political (a process known as *theoreticism*).

2. *Analytical processes.* Evidence is based on vivid and unusual single cases rather than probabilities derived from large samples; causality is ascribed in a black-and-white fashion to behavior from either dispositional or situational factors, and the fact that things may occur by chance is

ignored. This style of reasoning overestimates the popularity of one's opinions and attacks the integrity of opposing views and the scientific method in general (i.e., there is no perfect study and there are many sciences).

3. *Integration of evidence.* Evidence is integrated by declaring "what everybody knows," "I am telling you like it is," explanation by naming, exceptions prove the rule, theory is neglected to guide explanations, and adhering to an idiographic focus (i.e., relying on one case).

Fast-forward to the 21st century, and it is evident that common sense is in vogue to attack scientific knowledge especially in the social sciences (e.g., criminology, economics, education, psychology) and sometimes even in the *hard* sciences such as the environment (e.g., climate change) and medicine (e.g., immunization).

Our concern here is with the corrections field where psychological approaches have been the primary victim of knowledge destruction arguments. For example, psychological factors that can change over time (e.g., offender's attitudes, beliefs, personality) are alleged to be not important predictors of criminal behavior. Only static factors (e.g., criminal history) are useful; therefore, it is a waste of time to measure change in offenders for the purposes of rehabilitation since their behaviors are impervious to change. In addition, prediction of behavior may apply to groups but not individuals. Moreover, diagnostics based on actuarial measures (i.e., personality and risk measures) is a mechanistic process and dehumanizes the offender and the common-sense wisdom of the person assessing the offender.

Second, psychological treatment programs based on behavioral approaches are due to factors other than the treatment itself. Or, if they are positive results from treatment, the effects are deemed trivial as they have no impact on aggregate crime rates. Treatment studies have also been disparaged on methodological grounds: All treatment programs are fatally flawed because every study has unreliability in measurement of the independent and dependent variables and no treatment itself is implemented perfectly. Or worse, it is suggested that studies that claim

treatment programs are effective are biased since the authors who performed the studies also wrote the articles.

Third, the most effective means to reduce criminal behavior should promote fear in offenders by imposing longer and harsher prison sentences, more punitive sanctions on probation/parole violations and utilizing humiliation techniques (e.g., cross-dressing, wearing dunce caps). Another recommended strategy is *feel good* lifestyle activities (e.g., dog sledding, drama therapy, drum circles, horticulture, pet therapy, yoga).

Knowledge Construction

A knowledge construction approach contends that common sense can be mistaken even when applied to the routine activities people face during their everyday lives but is frequently in error when applied for want of a better term, to *complex* issues often found in the scientific domain. In this latter case, a pragmatic common sense is required to reach a conclusion that better reflects the truth of the matter. Individuals employing this form of common sense appreciate the need to acquire a thorough working knowledge of the methods of science and an in-depth understanding of the subject under discussion before offering an opinion. This attitude leads to knowledge construction—a process that best achieves the goals of science (i.e., knowledge, prediction, control, and replication of results).

The fundamentals of knowledge construction are as follows:

1. *Sources of knowledge:* Quantitative; derived from primary studies in the scientific literature.

2. *Analytical processes:* Surveys, correlational studies, quasi-experimental designs, and experimental designs with more confidence placed on results from studies that control threats to validity (i.e., history, maturation, selection bias, response bias, regression to the mean, instrumentation artifacts); meta-analysis for summarizing groups of studies with particular attention paid to providing an exact and precise estimate of the size of the effect; uncovering the influence of any moderator variables (e.g., design strength, treatment fidelity, individual differences) on the results.

3. *Integration of evidence:* Causality is complex, results are presented in probabilistic terms, expectations are that theory will be revised as more research uncovers new findings and are founded on large samples that are much more representative.

Knowledge cumulation efforts in corrections have spawned an impressive research literature, much of it employing meta-analysis, a statistical approach to reviewing research studies to reach general conclusions about *what works*. As a result, a theory has evolved that demonstrates treatments based on behavioral therapies that target the criminogenic needs (e.g., antisocial attitudes to a wide variety of human endeavors) of higher-risk offenders who are most at risk of committing crimes. The identification of risk is accomplished by using risk prediction instruments, which contain items that identify psychological behaviors of offenders that require intervention. And, since these behaviors are malleable, it is possible to monitor changes in risk over time for effective supervision of the offender.

Research on prisons has dispelled overly dramatic views about the effects of prisons and clarified the utility of the three theories of prison life. The evidence is persuasive that prisons do not serve as a deterrent to criminal behavior; in fact, prisons may increase it for certain types of offenders. The evidence also provides guidelines to manage prisons in a more safe and humane manner.

Finally, the use of meta-analysis, rather than qualitative approaches described previously, has identified a number of research design and statistical issues that need to be addressed (e.g., replication issues) to ensure a science of corrections grows in a constructive manner and is sustainable.

LARCENY/THEFT

Larceny/theft is a type of economic crime that involves the intentional taking of personal, tangible property from the lawful possessor with the intention of keeping the goods. The terms *larceny* and *theft* are generally used synonymously to refer broadly to the taking of an item from another with the intent to permanently deprive the owner of the item. Larceny/theft is commonly distinguished from robbery, which involves theft by force in a personal contact situation, and from burglary, which involves theft from a dwelling through unlawful entry. Larceny/theft makes up about 60% of all reported crimes in the United States with more than 7 million cases reported each year. This entry focuses on typologies and a criminological theory associated with larceny/theft.

Overview

Larceny/theft is one of the most common forms of crime. Broadly defined, larceny/theft refers to any form of unlawful deprivation of an item from its lawful possessor. However, larceny/theft is defined narrowly in official crime statistics, and by criminologists and crime typology scholars, as a distinct type of economic crime that involves theft without use of force, violence, or fraud. Larceny/theft is defined by the Federal Bureau of Investigation's Uniform Crime Reports

as the "unlawful taking, carrying, leading, or riding away of property from the possession of constructive possession of another," and the Bureau of Justice Statistics National Crime Victimization Survey defines larceny/theft as the "completed or attempted theft of property or cash without personal contact." Larceny/theft includes crimes such as shoplifting, pickpocketing, and purse-snatching. In official crime statistics, data on larceny/theft are often collected in a crime category separate from other types of economically motivated crimes such as motor vehicle theft, fraud, embezzlement, forgery, and robbery.

History of Larceny

Larceny/theft has been legally defined as a *crime* since common law times. Larceny follows suit after many other laws in America with its origins stemming back to the common law rule in England. The idea of larceny as a stand-alone offense category came after the establishment of robbery as a crime. Larceny was established as its own law given the nature of personal property that could be taken from individuals that may not fall into the category of robbery. There are varying types of larceny that can be committed that fall into categories of degrees in which punishments vary.

Aggravated larceny can be understood as the crime of larceny with the added use of an aggravating factor such as the use or threat of force

in the taking of an item from its lawful owner. *Simple larceny* is the term assigned to the commission of larceny without the use or threat of force to deprive the owner of their property. This would include the taking of goods that were unattended at the moment of their departure from the lawful owner's possession. *Grand larceny* is the term given to the crime of larceny that results in the taking of a certain dollar amount or higher. The value typically associated with grand larceny is anything over US\$100 but can be set as high as US\$1,000 depending on the state. The term *grand larceny* indicates that a felony has occurred, which indicates more severe punishments are warranted. On the other end of the spectrum is *petit larceny*, commonly known as *petty larceny*, in which the value of goods taken does not exceed US\$100, or depending on the state, up to US\$1,000. Petit larceny is indicative of a misdemeanor offense that will carry a significantly reduced sentence when compared to the felonious offense of grand larceny.

Punishments of Larceny

Punishments for larceny vary depending on state as well as federal laws. For example, some states classify grand larceny as the taking of items valued over US\$300, while petty larceny is valued under US\$300. The penalties for committing grand larceny in some states involve a felony conviction, a monetary fine of up to US\$5,000 and/or up to 5 years in prison. Penalties for petty larceny are less severe with fines up to US\$500 and/or up to 60 days in jail. These penalties can vary in sentencing but are the consistent parameters for each new offense regardless of the number of times such an offense has occurred. Other states, and the federal government, have varying penalties for larceny/theft crimes though punishments nationwide are generally similar in nature. Aggravating and mitigating factors are taken into consideration during the sentencing portion of any conviction. This would include, but is not limited to, the offender's mental capacity and criminal history as well as the level of force used to obtain the items.

Typology of Larceny

Larceny is a crime that is committed with the intention of gaining value by means of depriving the lawful owner of the items used. The person-on-property obtainment crimes establish themselves in their own homogenous category given the nature of their intended goal. Obtainment crimes are crimes committed by individuals who are seeking to take goods or property from other individuals or locations. Individuals who seek to achieve status in life or among their peer group characterize crimes of obtainment.

In comprehensive typologies of crime that conceptually categorize types of crime across a broad range of crime types (e.g., violent crime, sex crime, economic crime, political crime, copy-cat crime), larceny/theft is generally considered an economic crime. Most individuals who engage in larceny/theft are instrumentally motivated with the goal of economic gain. However, some types of larceny/theft such as shoplifting, while primarily economically driven, have been found to be associated with additional motives such as mental illness or emotional need such as stealing to support a substance abuse, compulsive stealing as a result of emotional disturbance, or impulsive stealing as a result of being under the influence of drugs or alcohol. Larceny/theft is an instrumental-economically motivated crime with secondary expressive motivation for some offenders.

Larceny/theft has been conceptualized differently by varying typology scholars, for example, Clinard, Quinney, and Wildeman (1994), with some classifying larceny under the broad category of *conventional criminal behavior*. Under this view, the crime of larceny is a heterogeneous crime category categorized with burglary and robbery as a crime against personal property. This category exists with the belief that offenders are rational decision makers given that their behaviors are consistent with the economic goals of society; however, their medium for obtaining their ends is socially unacceptable. Offenders who commit crimes of larceny/theft are typically subjected to rehabilitative programs that maintain the status quo rather than promoting actual change. Other typology scholars, for example, Miethe, McCorkle, and Listwan (2007), classify

larceny/theft as the “unlawful taking, carrying, leading, or riding away by stealth of property, other than a motor vehicle, from the possession of another” (p. 2). Rather than classifying larceny as a distinct crime type, these authors argue that the broad term of burglary covers all matters related to theft with the exception of motor vehicle theft.

The typology of an individual who might commit the crime of larceny can generally be described in two broad categories. The first category is the opportunistic individual, as many crimes of larceny are committed when the personal property of another becomes visibly available and the offender is able to quickly conduct a cost–benefit analysis that leans in favor of committing the crime, as a watchful guardian is not present. The second category of offenders can be understood as the manipulative individual who may work to obtain the personal property of another by way of conning, manipulation, or dishonesty. The target of an offender committing the crime of larceny is the property itself. An individual who participates in this category of crime might seek out a target that is deemed to be low risk or high value, or both.

Given the risks associated with the crime of larceny, there are two main categories of offenders who commit this type of crime. The first is the one-time offender who obtained an item illegally but is not likely to recidivate. Offenders within this category may be able to achieve rehabilitation and participate in society on an acceptable level. The other type of offender commonly seen in this category is the repeat offender, that is, the individual who continuously commits crimes of larceny with little regard as to the consequences. Repeat offenders often start committing crimes of larceny at young ages, often with their peer group associations. Peer group associations, such as gangs or a group of societal outcasts, often support the behavior observed with the crime of larceny as other members of the peer group may be committing crimes. Individuals within this peer group are also likely to engage in other forms of criminal behavior both at a young age and throughout their lifetime. The young, male offenders common in this category often experience arrests and convictions

throughout their lifetime and as such often find themselves on the lower end of the socioeconomic spectrum, thus perpetuating the cycle of repeated behavior given the inability to achieve a socially acceptable status through legitimate means. In addition, the crime of larceny may not be viewed as negatively on the spectrum of criminalized actions as the victim of this category of crime receives no physical, bodily harm in the commission of this crime.

Criminological Theory of Larceny

Routine activities theory finds its roots in deterrence or rational choice theory as its premise argues that criminal actions occur when the person, victim, and object of crime come together at one time. According to this theory, in order for crime to occur, three groups must align: the motivated offender group, the suitable targets of victimization group, and absent guardians of the personal property. In this case, a suitable guardian is required to be present in order to aid in deterrence efforts in this theory, and given the association with gangs that are also common with the crime of larceny, a guardian is unlikely to be present. Larceny/theft is most commonly found in areas where young, ethnic, and racial minorities, the poor, urban dwellers, and those who have recently moved to an area are likely to congregate.

Routine activities theory is but one of many theories that can be applied to the crime of larceny/theft, and though not exhaustive in nature, this theory is helpful for understanding the potential motivations for the specified offender class. This theory also provides insight as to what can be done to aid those individuals who may be more at risk than others. Individuals at risk are generally thought of as those who leave their home or belongings unattended during the evening hours when prowlers are likely to be present as well as those who own expensive, portable, belongings. In addition, a suitable target is likely to be one that can be easily observed by those wishing to commit this crime. Given the nature of the crime of larceny/theft typically being associated with valuable items in sight or in a vacant dwelling, some prevention tips include increased

lighting, vehicles at the residence, and sounds emanating from the home.

LAW ENFORCEMENT AGENCIES

Providing public safety and enforcing laws require more than one agency. Although lawmakers have created specific law enforcement organizations for different jurisdictions and offenses, criminal investigations and those responsible for conducting them are not always easily delineated. In those cases, agencies often work together as they protect the country and its citizens. This entry describes several U.S. law enforcement agencies by providing a brief organizational history including key figures, presenting the agency's current responsibilities, and describing typical work opportunities including qualifications necessary for employment.

Federal Law Enforcement

On September 11, 2001, two planes struck the World Trade Center in New York City, another plane crashed into the Pentagon, and a fourth

flight crashed into a Pennsylvania field. These attacks killed or injured thousands of American office workers, airline passengers, law enforcement personnel, and fire fighters. Many people wondered how this could have happened. With the intelligence resources available to the federal government, individual law enforcement agencies knew warning signs existed. However, many of these agencies underestimated the threat and failed to share information with each other. Eleven days after the attack, Pennsylvania governor Tom ridge, became the first director of the Office of Homeland Security. Since its inception, Homeland Security has focused on improving agency communications by housing 22 diverse agencies within its department. Although a few of these offices work as partners with law enforcement (e.g., Office of Intelligence and Analysis, the Federal Law Enforcement Training Center), only the U.S. Customs and Border Protection (CBP), U.S. Immigration and Customs Enforcement (ICE), and the U.S. Secret Service are responsible for law enforcement.

U.S. CBP

Like many federal law enforcement agencies, the current U.S. CBP division of Homeland Security has evolved since its creation in the late 1700s to regulate tax laws on imported products. According to its website, the Customs Division became primarily responsible for arresting tax evaders. In 1973, the Customs Division combined with the Special Agency Service creating the U.S. Customs Service. During the same time frame, Congress created the Border Patrol to guard inspection stations located on the land borders between the United States and Canada as well as the United States and Mexico. In 1932, the Border Patrol also started monitoring water ways, and by 1952, agents could search vehicles for undocumented individuals and illegal substances.

Transferred to Homeland Security in 2003, the CBP has worked to safeguard national security with its efforts in reducing the trafficking of illegal substances, weapons, and people and preventing undocumented individuals from entering the United States. At the same time, this agency tries to afford citizens and other documented individuals traveling in and out of the country with

minimal restrictions. In addition to employees, U.S. CBP also relies on technology (e.g., computer surveillance, unmanned aircraft systems) and physical infrastructure (e.g., gates, fences, and walls) to reduce the amount of drugs, weapons, money, and individuals being transported across the country's borders. As of 2017, the CBP employed 21,000 border agents with most of these agents assigned to the southwest border. In addition to searching for contraband, Border Patrol Agents are expected to identify terroristic threats and activities. At checkpoints, CBP officers search vehicles for human traffickers, contraband such as unlicensed products, drugs, weapons, and explosives.

In order to work for the CBP either as an agent or a border patrol officer, candidates must be in excellent health and pass a background check, drug test, and polygraph exam. Although not required, the CBP values applicants with previous military and law enforcement experience and bilingual skills. The CBP also hires experienced pilots as Air Interdiction Agents and experienced military boat captains as Marine Interdiction Agents. Their jobs are to monitor individual or group behaviors from the air and the water, respectively.

ICE

Although ICE has multiple responsibilities, the agency's major focus is on enforcing immigration laws related to travel to the United States. As discussed earlier, the Border Patrol apprehends undocumented immigrants and illegal materials at the border. In contrast, ICE agents usually apprehend undocumented individuals (as well as illegal merchandise) within the United States. ICE is also responsible for ensuring that companies are following legal employment guidelines for their workers and that undocumented individuals are not counterfeiting documentation such as social security cards and driver's licenses in order to gain employment. Within the agency, there is an investigative division (Homeland Security Investigations [HSI]) and an Enforcement and Removal Operations Division.

The HSI division identifies individuals, companies, and organizations believed to either support terrorism or engage in other criminal behaviors that can threaten national security. Other HSI

cases may include drug smuggling, child exploitation, and identity fraud. In addition to reviewing records, accounting data, and collecting information from some of the constituents described previously, the investigator may need to serve as an undercover operative.

Enforcement and Removal Operations is the division within ICE responsible for three steps of the immigration investigation process. First, agents identify individuals considered dangerous to either the general public or national security. Second, agents create a plan to detain those individuals in the United States that may include additional investigations and court proceedings. Finally, they organize the removal of undocumented individuals from the United States.

In addition to other agencies within Homeland Security, ICE identifies and prevents travelers with ties to terrorism from entering the country. Finally, ICE works with other agencies in preventing other countries from improper access to U.S. scientific and information technologies.

Applicants interested in becoming a criminal investigator need to be between the ages of 21 and 37 and have been a resident of the United States for at least 3 of the last 5 years. An exception to this last requirement exists for former government workers, veterans, and dependents of veterans stationed abroad. Because investigators are required to carry firearms, applicants cannot have been convicted of a misdemeanor crime of domestic violence nor can they have been convicted of a felony. If selected, all applicants must then complete basic training at the Federal Law Enforcement Training Center. In addition to being physically fit and willing to move to any location offered, investigators need to be able to travel.

One career opportunity in the Enforcement and Removal Operations division, an Immigration Enforcement Agent, is responsible for the removal and relocation of an identified person to his or her country of citizenship. Other agency positions within ICE include Criminal Research Specialists, Investigative Assistants, and Mission Support Specialists. These employees are responsible for providing information gained either through public or covert court-ordered access so that HSI agents can conduct their work. Many of the same requirements listed for the HSI Investigator also apply to these positions.

The Secret Service

Homeland Security also incorporated the Secret Service into its division that had previously been housed in the Treasury Department. Originally developed in 1865 to enforce the new laws related to counterfeiting, the Secret Service's responsibilities expanded to provide part-time protection for the president. The agency's role as a presidential defense team eventually increased to full time and included coverage of the vice president, president-elect and their families, visiting heads of foreign states. Congress allocated to the Secret Service the power to investigate threats as well as develop safety plans for gatherings involving protected members of government.

The Secret Service Counterfeit Division investigates and seeks to prevent the mass reproduction of the U.S. dollar. Technology (e.g., advanced computer printers, copiers, scanners, and specialty paper) and an increased use of the U.S. dollar in more foreign countries increase the likelihood of counterfeiting. Therefore, the Secret Service has worked with other countries to ensure that the detection of counterfeiting is consistent worldwide.

Also related to advances in and concerns with technology, the Secret Service has an internationally accredited advanced forensics laboratory. Law enforcement agencies can request information about inks, handwriting analysis, polygraph examinations, and fingerprints to name a few. Since 1994, the Secret Service has shared both forensic and technical information to any agency investigating missing or exploited children.

Several requirements exist for those individuals applying to be a Secret Service Agent of a Uniformed Division of the Secret Service. For non-veterans, applicants should be at least 21 and younger than 37 and have a current driver's license. Uncorrected vision must be better than or equal to 20/60 with correctable vision at 20/20. The Secret Service requires excellent health and physical fitness, and all applicants must pass a written examination. To gain Top Secret clearance, applicants have to pass a background check, a polygraph exam, an interview, and a drug screening. No visible tattoos are allowed on the head, face, neck, hands, and fingers. Other positions such as analysts, physical scientists, or public affair specialists require applicants to have 20/20

corrected vision and to pass background checks and, depending on the position, a medical exam and a polygraph test.

Federal Bureau of Investigation (FBI)

Of the agencies discussed, the FBI investigates the broadest selection of crimes. Examples include but are not limited to economic espionage (i.e., the stealing of corporate secrets or designs), corruption (e.g., law enforcement, campaign finance, and antitrust), and civil rights. However, the FBI was not always multidimensional.

In 1908, Attorney General Charles Bonaparte created the FBI within the Department of Justice. Unfortunately, the FBI was subject to the same corruption as other agencies at the time. In the 1920s, Assistant Director J. Edgar Hoover removed the unethical agents and increased the necessary requirements for employment in the FBI.

In addition to raising standards, Hoover's other goal involved using science in the investigative process. He combined fingerprint data from national and international law enforcement agencies into one searchable database and created a scientific laboratory. As early as 1932, technicians could use ultraviolet light, impression kits for creating molds, and cameras for examining physical evidence.

According to the FBI website, applicants need 3 years of full-time work experience and be willing to work anywhere in the world. Those with Certified Public Accounting certification or advanced degrees in law or other fields may be exempt from the first requirement. Preferences exist for applicants with certain degrees and experiences. Examples include but are not limited to scientists, military members with weapons or intelligence specialties, those with foreign language skills, and engineers. Applicants are also required to have excellent communication, leadership, and collaborative skills; be adaptable; and have good judgment. They are also expected to pass standardized physical fitness, vision, and hearing requirements. Once these minimum requirements are met, applicants begin a multi-phase process that includes cognitive and case analysis tests, multiple interviews, and background checks (including medical exams, drug testing, and polygraph exams). Candidates successfully completing these phases must then

graduate from the FBI Academy and serve a 2-year probationary term training in various specialty areas.

Other agencywide career opportunities involve degrees in the science, technology, engineering, and math fields. Examples include aerospace, biology, data science, geology, and network engineering. These opportunities include, but are not limited to, computer scientists, biologists, information technology specialists, and electronics technicians, and each position has its own requirements.

Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF)

In 1862, the Treasury Department's Bureau of Internal Revenue began collecting taxes and enforcing laws related to alcohol and tobacco sales. Once Congress passed the 18th Amendment to the U.S. Constitution prohibiting alcohol in 1919, this Bureau of Internal Revenue became responsible for enforcing prohibition. As did the previously discussed agencies, in 1930, the Prohibition Reorganization Act relocated the Bureau from the Treasury Department to the Department of Justice. At the same time, President Herbert Hoover announced an initiative to rid Chicago of Al Capone. This new Bureau of Prohibition and its well-known agent Eliot Ness worked with fellow agents in the FBI as well as the IRS to attack the growing crime in Chicago. After succeeding in arresting Capone, Ness continued his work by removing corrupt law enforcement agencies in Cincinnati and Cleveland.

Currently, the responsibilities of the Bureau of ATF involve investigating individuals and/or companies who illegally manufacture, distribute, or use alcohol, and/or tobacco products, firearms, and explosives. For products legally available to the public, the ATF licenses the distributors and, in the case of firearms and explosives, licenses the purchaser. The ATF also monitors the illegal sales of alcohol and tobacco to prevent a loss in income for those companies that are licensed.

Finally, because the ATF is also responsible for cases involving explosives, it also handle arson cases. Although arson fires are not always the result of explosives, many of the explosive experts use their knowledge and experiences to thoroughly investigate arson cases.

In addition to similar citizenship and age requirements of other law enforcement agencies, an ATF special agent applicant must complete an interview and pass an agent exam, a physical fitness test, and a drug test. A medical exam by an authorized physician verifies that the applicant has proportionate weight and height and is able to complete demanding physical duties without harming self or others. Applicants also have to pass a polygraph exam and be in compliance with the ATF drug policy (i.e., no current substance abuse or activities; prior experiences considered on a case-by-case basis). Other available careers include law, intelligence, research, administrative positions, and industry operations investigators. These investigators inspect company buildings, manufacturing procedures, sales records, and licensures within an industry (e.g., alcohol or firearms) to determine whether they meet ATF standards. Many of the hiring criteria are the same as the ATF agent; however, there are no age limitations, and investigators should expect frequent overnight trips each month.

U.S. Marshals Service

In 2016, the U.S. Marshals Service had over 5,000 employees across the United States. They arrest fugitives who are wanted for federal crimes, sexual offenses, murder, and organized crime. In addition, U.S. Marshals are responsible for many other duties. Former law enforcement officers are now employed in the U.S. Marshals service guard judges and court houses, federal prosecutors, and federal public defenders. These agents also evaluate construction plans and process to protect legal personnel once buildings are complete. Agents in Asset Forfeiture collect money and items from individuals and/or companies who have committed fraud. In the Justice Prisoner and Alien Transportation System, agents are responsible for moving prisoners between districts, prisons, and countries. Agents in the Prisoner Operations division contract with state and local prisons to house and monitor federal prisoners. Individuals who participate in special missions for the U.S. Marshals serve in the Tactical Operation Unit and often travel across the United States. Finally, U.S. Marshals within the Witness Security division are responsible for protecting government witnesses and their families as well as cooperating defendants.

To be a U.S. Marshal in any of its divisions, an individual must be a U.S. citizen between the ages of 21 and 36 and be appointed before his or her 37th birthday. Candidates are expected to have either a bachelor's degree or 1 year of experience or a combination of both that equates with a GL-07 (Government Level status). Experiences equivalent to this level include (a) good communication skills with individuals including prisoners; (b) criminal investigation skills including, for example, arrests and firearm use; (c) report writing; and (d) executing warrants. Individuals qualifying for this level also have at least some graduate-level education related to law enforcement or a field that would improve work performance and have exemplary grades in those courses. Applicants have to pass all required physical tests, written tests, and interviews and meet agency medical qualifications. Finally, individuals who pass all of the previously mentioned requirements must pass a 21-week course at the U.S. Marshal's Academy.

State and Local Law Enforcement

Although these are separate entities, the Bureau of Justice Statistics has combined state and local agencies for the purpose of statistical reporting. Therefore, the information across the agencies is presented similarly here.

While some may consider a job as a state or local police officer the *safest* law enforcement career to have, in reality, these individuals are often on the frontlines when it comes to drug use and distribution. This is especially important when local, state, and federal officers are working together to attack crimes related to organized crime such as human trafficking. Local police are often the ones who investigate domestic violence or crimes committed by individuals who are mentally ill. Although departments with 100 or more employees have multiple departments dedicated to particular crimes such as homicide, most agencies have 10 or fewer officers in their stations.

At the same time, they are often expected to create liaisons with community members in order to increase citizens' trust in the police. This is especially important because local officers are not immune to changes in the public's perceptions of the police. To increase safety for suspects as well as officers, many agencies have turned to technology. Cell phone video of law enforcement officers' arrests has

led to accusations of unnecessary force. As a result, the number of officers using TASERs or stun guns and wearing body cameras has increased. The use of this technology allows officers to (a) use less lethal force and (b) show another camera viewpoint during an arrest. Other technology available to police includes public surveillance cameras and automatic license plate readers. Finally, local officers are more likely to wear protective body armor and use in-field computers for creating incident reports.

Law enforcement training is often categorized as either stress based (i.e., a military style training with extreme physical and psychological components) or a nonstress based (i.e., an academically focused and mentor supported approach that still includes physical training). Most facilities offer basic training that falls somewhere between these extremes. Lasting 21 weeks, training modules include patrolling, investigations, emergency vehicle operations, and case reporting. Training for officer candidates also includes weaponry and defensive strategies.

Many state and local departments have similar age, physical fitness, driver's license, and polygraph testing requirements. Candidates should have good character and must not have a driving while intoxicated or driving under the influence within 2 years before beginning training. Applicants must have a high school diploma or a GED. In addition to passing both medical and mental exams, candidates must have good enough vision and hearing to perform duties satisfactorily.

Cybercrime: Law Enforcement Collaboration

The Department of Homeland Security has published several resources that emphasize the importance of law enforcement agencies working collaboratively. Subdivisions within Homeland Security also offer funding to those local law enforcement agencies that need extra personnel for either temporary or long-term investigations. For example, CBP does not work alone but often shares information, resources, and the work with state patrols and local police, especially from the border states. In addition, the CBP works with ICE to share information, resources, and strategies concerning border activities. Multiple agencies have analysts, computer programmers, and technicians who are

able to work together using the very Internet systems they are trying to protect.

In response to the 2001 PATRIOT Act, the Secret Service director developed the Electronic Crimes Task Force. The Electronic Crimes Task Force investigates frauds and cybercrime that may be related to illegal banking or terrorist activity. The Cyber Operations division investigates instances of computer viruses and hacking.

The FBI also participates in statewide, national, and international cyber task forces. In addition to fixing the effects of ransomware and computer and network hacking, the FBI also creates sting operations for identifying and arresting individuals involved with child pornography, human trafficking, child sex tourism, and terrorism.

There will always be a need for law enforcement specialties as well as the ability for agencies to collaborate across state lines and borders. As the needs of the country and world have changed, so have law enforcement agencies.

LAW ENFORCEMENT EMPLOYMENT SCREENING

Screening candidates for law enforcement employment is a matter of risk assessment. The agency views risk from the lens of vicarious liability (i.e., the legal responsibility one has for the hiring of unqualified personnel). Were the applicant to be hired and a civil suit result from an officer's intentional or negligent action, the agency, and its executive director, would likely be named as parties in that suit. In a much broader sense, there is inherent risk associated with hiring an individual who is inept at protecting the public. Any mistakes the officer makes reflect on the integrity of the agency. In order to try to find the best applicants, law enforcement agencies often employ a *multiple hurdles* selection process.

A multiple hurdles approach is a conventional preemployment practice used by most agencies; it requires applicants to pass each stage of the hiring process to advance to final consideration for employment. Failure to satisfactorily clear any hurdle will generally remove the candidate from further consideration. While some agency policies differ in their manner of execution, there are established norms within the profession. This entry describes each stage of the multiple hurdles approach in the law enforcement screening process, then concludes with an examination of public policy recommendations that might allow agencies to further evaluate their preemployment process.

Multiple Hurdles Approach

Most police agencies utilize the multiple hurdles approach as a risk assessment mechanism, thus

increasing the likelihood of selecting the best candidate for police work. Ultimately, each element of the hiring process has a hurdle the candidate must clear to advance. Thus, the collective criteria that comprise the multiple hurdles hiring process are their own individual risk assessment. Each hurdle or stage provides actuarial information about the risk or benefit posed by each candidate and assists police executives in predicting whether the candidate will be successful in a law enforcement setting. Each stage should be a fair assessment of the type of skills necessary to be successful in today's law enforcement setting.

The individual hurdles function as mini-risk assessment tools, and the entire set of hurdles should inform the overall hiring decision. Collectively, this risk assessment tool has been used to narrow the focus of desired police officer characteristics and has been shown to reduce discrimination claims. Each subsequent hurdle in the process is designed to be more intrusive, more time-consuming, and thus, more expensive. In contrast to a multiple hurdles approach, a compensatory approach would allow a high score on one hurdle to compensate for a low score on another.

As previously mentioned, there are numerous items that agencies utilize in the selection process. Although not exhaustive, established norms of multiple hurdles for selection include (a) personality inventories, (b) physical tests, (c) targeted interviews, (d) unstructured interviews, (e) paper-and-pencil honesty tests, (f) cognitive ability tests, (g) weighted application blanks, (h) polygraph and other credibility assessment tests, (i) personal and work references, (j) drug tests, and (k) medical examinations. These elements must be fair, valid, and relevant to police work and must contain some measure of reliability to enhance an agency's hiring process.

Employment Advertisement

Law enforcement agencies announce hiring in a variety of ways. Some advertise in digital and print media, whereas others post vacancies on their government entity website. Recruiters attend police association meetings and visit universities that offer criminal justice, law, and psychology majors. With the U.S. involvement with the war on terrorism, numerous agencies have placed high

demand on recently discharged veterans. Meta-analysis results suggest that prior military experience is unrelated to subsequent law enforcement performance. However, civil service systems in many jurisdictions give veterans *bonus* points on written exams. Large agencies have recruiting divisions dedicated to attracting qualified personnel to the police profession and to their agency. Within this context, agencies often engage in affirmative action efforts to encourage female and minority applicants to consider a career in law enforcement. These efforts can greatly contribute to the development of a diverse workforce.

Screening Interview and Records Queries

Once an applicant and an agency connect about a job opening, the candidate usually completes an initial application. Some applications are completed online, but more often they are conducted at the hiring agency's recruiting office. This provides the recruiter a chance to meet the applicant, and the interview is complemented with a quick *go-no go* query as to whether the candidate has engaged in disqualifying behaviors. Most hiring agencies have a list of behaviors they consider disqualifying, including recent or excessive illegal drug use, felony arrests or felony crime involvement, driving while intoxicated convictions, domestic violence convictions, and certain civil judgments (e.g., bankruptcy). If an applicant admits to engaging in a disqualifying behavior, he or she is generally disqualified without further consideration. Some disqualifiers are permanent (e.g., certain felony crimes, certain types of drugs used). Many, however, are time-delimited, only temporarily barring the applicant from consideration (e.g., driver license suspensions, minor recent drug experimentation). If the candidate denies engaging in disqualifying behaviors, he or she moves on in the hiring process.

Extensive research goes into investigating and reviewing the driving and criminal history of each applicant. This is accompanied by criminal and civil records checks. The purpose of these inquiries is to determine whether the applicant has been arrested for, or convicted of, any crime, including certain traffic-related violations. Many misdemeanor crimes are not immediately disqualifying, while certain others are. For example, it is

common practice to immediately disqualify an applicant for any domestic violence conviction because persons convicted of such crimes cannot carry a firearm. Civil records checks allow employers to identify early on if there are areas for potential concern (e.g., past or pending bankruptcy, delinquent child support payments, pending civil lawsuits). Along with protecting the agency and society, police executives save time and money by identifying unqualified applicants early in the process.

Written Aptitude Testing

Police screening research has shown that scores on cognitive ability tests are a good predictor of future job performance, especially performance in the academy. Coping with stressful situations is one of many facets of law enforcement. In today's evolving society, agencies seek and pursue individuals capable of not only handling the physical demands of police work but also those who possess the intellect to learn the law, navigate technology, and solve complex issues. Core competencies such as mathematical and verbal reasoning are integral skill sets to the police profession and can be tested in a variety of formats. For example, the National Criminal Justice Officer Selection Inventory is a common aptitude test that can be used to predict candidate success in law enforcement settings. The National Criminal Justice Officer Selection Inventory tests areas such as problem-solving, reading comprehension, mathematics, and writing ability. These skills are essential to successfully completing most police academies and are needed to be successful in the law enforcement profession.

Conventional modalities for testing include paper and pencil, pen essay, and computerized assessment. Cognitive ability tests are used because most police officers enter the profession as *street cops*, and reading and math acuity become valuable skills in such areas as report writing and accident reconstruction. Language reasoning should also be assessed, as it contributes to the effectiveness of interpersonal communication and courtroom testimony. Defense attorneys are quick to point out the inaccuracies of a weak investigation, while prosecutors desire an officer that possesses a strong command of job knowledge.

As officers gain tenure, they often desire to specialize in select areas of criminal investigations. Larger agencies offer disciplines in crime scene investigations, narcotics investigations, computer forensics, financial crimes, and many other specialties. As a risk assessment tool, base-level performance protects both officer and agency from vicarious liability. Academic screening tests also ensure the public that the officer possesses the necessary faculties to function adequately and safely in the job.

Physical Agility

One critical aspect of police applicant screening is the physical agility test. Pushing cars from intersections and chasing fleeing criminals on foot are not unusual endeavors for the average police officer. When it comes to physical agility testing, the choice of methods is agency-specific. Some agencies use standardized calisthenics and running tests to assess an applicant's minimum competency level. Obstacle courses may be implemented, with the addition of work-related scenarios the agency considers relevant to the job function. These work-related tasks include such things as jumping out of the seated position in a police car and sprinting; climbing walls, ladders, or steps; and crawling under low walls.

Concerns have been raised about the fairness of physical agility testing, particularly in the realm of female screening. Some law enforcement agencies have even suspended physical agility testing while engaged in federal lawsuits over the equality of such requirements. These lawsuits contend the test is biased against female applicants, with a lesser percentage of females passing than their male counterparts. To better assess agility, many police agencies send proctors through rigorous programs (e.g., the Cooper Institute) that certify officers as *law enforcement fitness specialists*. The programs enhance the testing by identifying standardized agility protocols, therefore allowing the agency to better mitigate risk-related issues such as injury prevention. Advanced courses teach instructors to measure the body mass index of a candidate and implement nutritional strategies designed to prepare the candidate for the physical challenges of the test.

A key issue in physical agility testing is whether the agency is trying to measure physical ability versus physical fitness. The use of physical ability tests assumes that there are certain minimal standards that an officer has to meet to properly perform the job. For example, an officer who can't drag a 150-pound dummy 20 ft might not be able to save a person trapped in a burning car. With physical ability tests, separate sex or age norms are not used because there is a minimum standard that must be met.

In contrast, physical fitness tests determine things such as the cardiovascular fitness. In such cases, it is not unusual for an agency to use separate sex and age standards.

Firearms Proficiency Training

Some agencies hire *lateral transfer* candidates from other law enforcement agencies. These are people already trained and certified as police officers in the state in which they are applying. At this point in the hiring process, many agencies will require the lateral applicant to qualify with his or her service weapon. Firearms qualification courses often include shooting at varying distances (e.g., 3, 5, 7, 15, and 25 yards) with additional combat courses that address *shoot-no shoot* scenarios. Some agencies may require the lateral transfer candidates to demonstrate familiarity and proficiency with a standard police issue shotgun.

Personal History Questionnaire/Background Booklet

During the initial testing phase, the candidate will be asked to complete a personal history questionnaire. These are lengthy booklets that cover many aspects of the candidate's life and commonly begin with listing the applicant's immediate family members and their contact information. Background investigators will normally contact these family members and ask specific questions about the candidate's upbringing, his or her associates, and habits—both good and bad. To further the scope and depth of the background investigation, many agencies will conduct criminal history checks on immediate family members. The candidate will usually need to list all addresses where they have lived, including academic institutions and military

installations. Background investigators will interview the applicant's friends, neighbors, even teachers at institutions where he or she went to school. Previous work history will be verified as well as any work-related disciplinary actions the applicant received while at the place of employment. The background questionnaire usually asks about current debt and asks the candidate to obtain a recent credit check from one of the large credit reporting companies. Applicants with large debt may be disqualified, particularly if he or she has a history of delinquency in repayment.

The background questionnaire will often have the applicant list all illegal drug contact, experimentation, and use. The applicant will be asked to list all criminal acts they have committed. Potential law enforcement employers often ask about alcohol use and gambling frequency. Both of these can be predictive of future problems. The applicant will usually have to sign a waiver and release of information form that allows investigators access to his or her personal education and employment records. These are often notarized for legal reasons.

Personal History Booklet (PHB) Review

A recruiter or background investigator will schedule an appointment where the candidate will return the PHB and allied documentation. Often this documentation includes a copy of his or her high school diploma, official transcripts from colleges attended, a credit history check, military service verification such as a DD-214, financial loan paperwork, and any civil court records (e.g., name changes, marriage certificates, divorce documentation, liens, judgments, and civil suits). The agency representative will review the PHB with the applicant and ensure all required documentation accompanies the package. Most agencies will not accept incomplete packages and will return the PHB to the applicant, oftentimes suspending the process until the documents are complete.

Background Investigation

Once the agency has accepted the application package, it schedules a background investigation, depending on the hiring needs. The depth and breadth of the background investigation can vary

considerably. Larger law enforcement agencies, including federal, state, and large municipalities may employ full-time background investigators. These officers specialize in conducting background investigations, and this is their primary duty. Because they are familiar with these specialized investigations, they are efficient at getting them completed in a timely manner.

The background investigator will often start by conducting a more in-depth criminal records check, including records on national and local databases. The investigator will contact the local law enforcement agencies in jurisdictions where the applicant has lived, worked, or attended school and ask these agencies to check local *in-house* databases for any contact with the applicant. One of the reasons for conducting a credit check is that it often provides clues as to where a person has lived or worked. Background investigators then use the credit history to help locate law enforcement agencies, friends, neighbors, and teachers to interview.

The investigator will also conduct extensive driving history checks. Driving records inform agencies about past driving citations, accidents, and arrests. One of the predictors of potential problem performers in law enforcement is a past history of rule breaking, and having numerous driving citations is considered as such. Most hiring agencies will be allowing employees to operate agency-owned motor vehicles, and a history of being aggressive- or citation-prone will drive up the cost of insurance. Many agencies are not willing to accept the risk of someone with a poor driving history nor are they willing to pay additional insurance premiums because of bad driving habits.

The investigator will contact as many former employers as possible to verify what the candidate listed in the PHB and is usually most interested in reviewing employment applications for additional leads: length of employment, promotions, performance evaluations, and disciplinary actions. The investigator will compare this information to what the subject listed in the PHB. All of these will help the investigator assess the applicant's work performance and work attitude, as well as his or her honesty. Applicants have been known to omit prior places of employment where they received negative disciplinary actions or from which they were terminated.

Once the records check portion of the background investigation is complete, the investigator often plans field and telephonic interviews using what he or she learned through the records check. The investigator may start with immediate family members including spouses, parents, and siblings as well as people with whom the applicant has lived, including roommates and former military coworkers. They schedule appointments with friends, prior employers, coaches, teachers, guidance counselors, and sometimes former coworkers. They seek to verify what the applicant has stated in the PHB and identify any possible areas of concern. Ultimately, the psychologist conducting the suitability assessment will use information gleaned in this stage to help guide the clinical interview and inform the assessment. Background investigators may travel to other cities to meet with these potential sources of information, depending on the recruiting budget.

Once the records check and personnel interviews are complete, the background investigator will start to finalize the report. It is not unusual for the investigator to contact the applicant for clarification and additional information. It is helpful to the investigator, and the investigation, for the applicant to take an active role in getting the information the background investigator needs to complete his or her task. If the applicant does not help, the background report may not get completed. Once the background report is complete, the investigator usually gives it to his or her supervisor to review. Supervisors will *sign off* on the report and forward it to the recruiting office where they often then schedule a follow-up interview and credibility assessment test.

Credibility Assessment Interview

The hurdle many applicants find most concerning is the credibility assessment interview and test. This stage usually consists of some form of veracity verification test. These tests, which include polygraph and EyeDetect (i.e., ocular-motor detection of deception), are not without controversy. Their utility and validity have been, and continue to be, the subject of polemic arguments. Proponents extol the benefits of increased disclosure, deterrence, and diagnostic value. Opponents claim the false-positive rates (i.e., where a truthful

subject fails the test) are unacceptable. Still, many agencies will require an applicant to submit to some form of credibility assessment test that he or she must *pass*.

The polygraph is the oldest of the validated credibility assessment tools in current use. Polygraph screening has been used to screen law enforcement officers since around 1945. Modern polygraph instruments measure movement associated with breathing, relative blood pressure changes, sweat gland activity, and blood pulse volume changes. They include other sensors to help gauge level of cooperation. The underlying theory of the polygraph is that physiological changes happen in response to test questions, and the magnitude of those changes is commensurate with the salience of the test question. The salience of the question depends on the degree to which the question challenges the subject's goal of passing the test. The physiologic responses load differentially on groups of questions, as a function of truth-telling or deception.

There are several variants of polygraph testing, but the most common version is called the *Comparison Question Testing* format. Within the family of the Comparison Question Testing, there are several polygraph techniques and differences between the variants are often minor. A polygraph technique consists of two parts: the data collection portion and the test data analysis phase. Validity studies have to report both phases of the technique to properly identify it. The data collection phases for techniques can differ in terms of the number and scope of the test questions. From a validation perspective, better tests generally result from fewer, more distinct questions. The test data analysis phase is the part where the collected data get analyzed. This can be done by the human polygraph examiner as well as by a computer algorithm. While there are a number of test data analysis models in use, the better performing models tend to be less subjective and thus have greater interrater reliability.

Polygraph screening test questions should target actuarial behaviors (i.e., those behaviors that are related to good or poor police performance). However, some agencies try to address *values-based* behaviors that are not predictive of performance. Police administrators and decision makers should endeavor to identify past behaviors

that predict performance and develop their polygraph questions that address each behavior. For example, questions targeting work-related disciplines and acts of physical domestic violence would seem appropriate performance predictors.

Comparison Question Testing format screening polygraph techniques have peer-reviewed reported accuracy in the 80% range. They are well above chance at detecting deception, though far from perfect. End users should be cautious about making hiring decisions based on the results of a polygraph test alone since there are many variables that affect the ultimate accuracy of any particular test. Positive results (i.e., failed test) should be followed up with additional discussion, investigation, and testing, ideally with a different credibility assessment tool.

The base rate of deception is often an overlooked consideration in credibility assessment testing. Base rate is the probability any given individual in a testing population will be positive for the issue of concern. In credibility assessment testing contexts, this means the number of people in the testing population who are lying with regard to the target issues. As referenced in numerous studies, target issues can vary considerably. If young U.S. adults are being tested for drug experimentation in their lifetime, a higher base rate of that activity would be expected, compared to engaging in espionage or terrorist activities, for example. If that group is then applying for a job with very strict guidelines for lifetime drug experimentation, a higher base rate of deception could be expected. If espionage or sabotage among that same group was being tested, a much lower base rate of engaging in those behaviors would be expected and thus a lower base rate of deception with regard to those targets. Since all credibility assessment testing is imperfect, base rates can play a big role in the types of errors made. If testing a low base rate behavior, such as espionage or sabotage, the majority of the positive (i.e., failed) results should be false positive. Operationally defined, this means people who had not engaged in the behavior still failed the test. Alternatively, if a high base rate behavior was tested, such as denial of alcohol use by U.S. college students, most of the errors would be false negative, indicting the lies passed undetected.

Using an alternative technology in a *successive-hurdles* model can help adjust the base rates to improve subsequent credibility assessment testing. EyeDetect is one proven technology that can be used in the early stages of the hiring process as a stand-alone credibility assessment tool. EyeDetect can also be used to adjust the base rates for subsequent testing, for example, with polygraph. Adjusting the base rates of subsequent testing reduces the types of errors made, depending on the testing goal. EyeDetect works by having the subject read a series of questions; the subject then answers *yes* or *no* by pressing a button or computer key. During the reading exercise, the EyeDetect measures a number of reading behaviors, physiologic measures, and answering behaviors. The software combines these measures and produces a credibility score ranging from 0 to 99, with increasing values being more indicative of truth-telling. Peer-reviewed studies of EyeDetect show accuracy in the mid-80% range. Research also suggests that combining two different screening technologies, such as polygraph and EyeDetect, can reduce desired errors to around 2%.

Follow-Up Interviews

Once the credibility assessment testing phase is complete, a recruiter meets with the candidate to discuss any issues that arose during the background investigation or credibility assessment testing. Sometimes the background investigator or recruiter may have to conduct additional interviews to assess the issues raised. This often means the candidate is invited back for follow-up credibility assessment testing. If there are outstanding issues and concerns, most supervisors will not allow a candidate to move forward unless all information gathering avenues have been exhausted. That means the background package will sit in *limbo* until the issue is resolved.

Conditional Offer of Employment

At this phase, someone senior within the hiring authority will usually review the entire application package. If this person feels the candidate is acceptable, a *conditional* offer of employment will be made (i.e., the offer depends upon successful completion of the medical and psychological

assessment phases). This is done in order to be compliant with the Americans With Disabilities Act of 1990, which provides protection against discrimination for people with disabilities. The act applies to federal, state, and private employers with 15 or more employees; it expressly prohibits employers from asking applicants about medical history during the preoffer stage in order to prevent potential employers from asking questions that might reveal a disability that could be used to disqualify the applicant from the hiring process. The Americans With Disabilities Act also prohibits potential employers from requiring applicants to undergo medical examinations and from asking questions that could disclose a disability before offering them a job. Employers usually wait until they are ready to extend a bona fide employment offer before asking the candidate to submit to medical and psychological queries.

Psychological Suitability Assessment

The hiring agency is likely to have the candidate assessed for psychological suitability for law enforcement work. Police work can be extremely stressful and requires good interpersonal relation skills. The work can place the officer in highly dangerous situations that require fast and correct decision-making skills. This psychological evaluation can also be a very stressful stage of the hiring for the applicant due to the potentially subjective nature of the decision-making process. The psychologist should be familiar with police work, have expertise in assessing maladaptive behaviors, and be proficient with the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5). Examinations should be designed to identify psychopathology and personality disorders that would be incompatible with law enforcement work. Items such as impulse control, ability to deal with supervision, and motivation to choose law enforcement as a career are core features on most psychological suitability inventories. The examinations usually consist of a series of standardized psychological tests and a clinical interview. The psychologist will usually review the background investigation, the PHB, the credibility assessment testing reports, standardized psychological test results, and notes from the clinical interview when writing the report. The

psychologist oftentimes works in conjunction with the polygraph examiner and background investigator to ensure a unity of effort and proof of screening concept.

Numerous psychological tests have been developed in an effort to screen out candidates with psychological issues that could make them a danger to themselves or others. Although many assessments are available to test psychopathology, two commonly used inventories in law enforcement selection are the Minnesota Multi-Phasic Personality Inventory-2 and California Personality Inventory. The Minnesota Multi-Phasic Personality Inventory-2 consists of 567 true/false items and is commonly used to test an individual's suitability for high-risk public safety positions. Although widely utilized, concerns have surfaced regarding the validity of specific scales relating to the Minnesota Multi-Phasic Personality Inventory-2. Elements that enhance psychological inventories continue to evolve, yet the primary agent of responsibility lies with the mental health professional. Along with credibility assessment, psychological suitability remains an integral area of screening that police administrators rely on for final hiring decisions.

Medical Suitability Assessment and Drug Testing

At this stage, a medical professional usually conducts an examination to determine whether the applicant is medically suitable for the job. Typically, a detailed job description is provided to the medical professional so that he or she can determine whether the applicant is capable of performing the critical job tasks. These physical examinations can be quite extensive and often include vision and hearing testing, cardiovascular assessment, including an electrocardiogram, dermatological examinations, endocrine system assessments, hematology–oncology screening, musculoskeletal assessments, respiratory system assessment, infectious disease assessment, and a neurologic evaluation. In addition, candidates typically are required to undergo drug testing.

Approved for Hire: Selected/Not Selected

At this point, all aspects of the candidate's background investigation are assembled and reviewed. Some agency executives choose to take on this task

themselves, while others delegate it to a trusted subordinate. If the candidate is deemed sufficiently trustworthy, he or she will be considered *approved for hire*. Often agencies will develop lists of qualified candidates they keep for a specified period of time and will often approve more people than they need. As availabilities arise throughout the life of the list, the agency can contact an approved person to make a job offer. Some agencies will conduct *mini-background* investigations to fill in the time between when the person was approved and when that person gets his or her job offer.

Final Thoughts

Executives within police agencies are continually seeking the best methodology for screening candidates. Now policy makers face difficult issues surrounding vicarious liability and negligent hiring, often affecting external stakeholders. Translated, this means each element in the preemployment process must remain valid, fair, and impartial to each applicant, while enhancing the utility of screening methods.

LEVEL OF SERVICE INVENTORY (LSI)

The LSI is a risk assessment instrument that was designed to identify adult offenders' likelihood of reoffending. As such, it is one of a number of

offender risk assessment tools that are now used by a wide range of correctional, forensic, and mental health professionals who are given the difficult task of predicting offender recidivism. Various versions of the LSI are now used extensively in Canada, the United States, and various countries in Europe, Asia, and Oceania, in large part because they have demonstrated their capacity to predict offender recidivism among a wide range of offenders and they shed light on areas that correctional officials should target with the offender to reduce his or her likelihood of recidivating. Consequently, the LSI is described as a *risk/need scale* in that it assesses both the overall risk that an offender presents in terms of likelihood to recidivate and the *criminogenic needs* that might be addressed to reduce that risk. This entry describes the origins and history of the LSI, its theoretical and empirical basis, its design and content, and its research support.

Origins and History

The original LSI was developed in the early 1980s by Donald Andrews, in Ottawa, Canada, with the cooperation of the Ontario Ministry of Correctional Services. Andrews was originally interested in assisting the Ministry to establish supervision standards for probation officers. He was intrigued by the work of Sally Rogers, a Ministry researcher, who came up with a simplified instrument that effectively identified offenders who recidivated at both above average and below average rates of recidivism. Rogers's 6-item scale asked yes–no questions about offenders' demographics and criminal history (i.e., male, under 24 years of age, have criminal record, have delinquent associates, aimless use of leisure time, have family on social assistance). But Andrews was aware of more complex tools that had been developed in the United States, including the Salient Factor Score. He also believed that an instrument that was grounded in a sound theory of criminal behavior could do a better job of prediction. This led to his first effort, known originally as the *Level of Supervision Inventory*, an offender risk assessment tool that was guided by various theories about criminal behavior and empirical evidence.

The Theoretical and Empirical Foundations

Andrews was strongly influenced by the differential association theory of Edwin Sutherland and Donald Cressey and its more behavioral reformulations and by Albert Bandura's more general social learning theory. Differential association purported that criminal behavior was a learned behavior and that such learning took place primarily among intimate personal groups. Donald Akers then applied more Skinnerian terminology emphasizing the rewards and punishments that occurred as consequences of antisocial behavior, while Bandura introduced the concept of modeling (i.e., behavior, including antisocial behavior, can be learned by simply observing others and is strengthened when the model is rewarded).

This led to Andrews considering not only delinquent and criminal history as factors in a risk assessment tool but also an offender's history of support and punishment for both prosocial and antisocial behavior. He envisioned the brain as an unconscious computer, which routinely tallies all of the rewards and punishments (i.e., positive and negative consequences) for different kinds of behavior. However, the nature of the recent or current environment in which the offender is living is most important as it constantly provides a wide variety of rewards and punishment to a wide range of behavior. He reasoned that these rewards and punishments come in the form of material gain or loss, social or interpersonal support or criticism, and intrapersonal thoughts (congratulatory or critical) about the offender's behavior after the behavior has been performed. Andrews formalized this conceptualization as the Personal, Interpersonal Community–Reinforcement (PIC-R) perspective of criminal behavior. Years later, based on their appreciation of personality and attitudes, Andrews and James Bonta expanded the PIC-R concept by including it in a more integrated theoretical model of criminal behavior called a *general personality and cognitive social learning* perspective of human behavior including criminal behavior, which helped to frame the LSI and its successors.

Another important development by Andrews and Bonta, along with Robert Hoge, that spoke directly to the development and evolution of the LSI was the empirically derived principles of risk, need, and responsivity. The risk principle directs

correctional workers to focus their supervision and attention on moderate- and high-risk offenders. The need principle directs correctional workers to target the identified criminogenic needs of an offender in his or her rehabilitation process. The responsivity principle directs workers to adjust their style of interaction with offenders according to the offenders' cognitive, personality, motivational, and demographic characteristics so as to optimize supervision and intervention efforts. GPSLC and risk, need, and responsivity also comprise the backbone of what Andrews and Bonta have referred to as the *psychology of criminal conduct*. The development of these concepts occurred hand in glove with the LSI and its subsequent revisions. Therefore, a good understanding of the PIC-R model, the risk-need-responsivity principles, and the general personality and cognitive social learning perspective is needed in order to appreciate the LSI, its content, and its evolution over time.

It is important to note that PIC-R and the general personality and cognitive social learning were strongly supported by empirical research, most of which was psychological, sociological, and criminological in nature. Some of this work harkened back to classical, cross-sectional comparison of delinquents and nondelinquents conducted by Sheldon and Eleanor Glueck in the 1940s and 1950s, in which the two groups were found to be different on a wide array of dimensions, including attitude, disposition or personality, school behavior and performance, relationship with and supervision by parents, and peer relations. In 1969, a second major empirical study by Travis Hirschi revealed a similar list of characteristics that differentiated delinquents from nondelinquents and guided Andrews in his initial effort to develop a risk assessment tool. Numerous similar studies followed, allowing Andrews and others, including Paul Gendreau, to conduct meta-analyses of the predictors of criminal behavior and recidivism that continued to guide subsequent versions of the LSI through the 1990s and 2000s.

Rationale for Development

With the rise of offenders requiring community supervision and growing caseloads for probation officers, it had become clear that some means

were required to direct the increasingly scarce supervision resources to offenders who were at highest risk of recidivating. Moreover, evidence was emerging that the kind of service and the specific focus of intervention was important to the success of offenders in the community. In other words, to which offenders should probation officers devote their attention (risk principle) and on what issues should that attention focus (need principle)?

Until the early 1980s, those questions were addressed neither by theoretically sound or empirically driven practices. Instead, offender risk assessments were of two types: either they were based on subjective professional judgment, which, it was being learned, were little better than chance and were described as the *first generation* of risk assessment by Bonta or they were based on historical or demographic characteristics that were not subject to change and were described as *second generation* risk assessments. Although second generation risk assessments did offer assistance in terms of suggesting the amount of supervision (i.e., more supervision for high-risk offenders), such as the Salient Factor Score in the United States or Joan Nuffield's Statistical Information on Recidivism Scale in Canada, they did not offer any direction to the correctional worker in terms of the content of supervision simply because they consisted only of nonchangeable, static risk factors. Meanwhile, traditional psychological offender assessments were based on personality characteristics that had little or nothing to do with criminal behavior. The LSI was designed to rectify these shortcomings by offering a tool with practical value to correctional workers and their agencies.

The LSI is described as a *third generation* or risk/need assessment tool since it includes both static risk items and dynamic (i.e., changeable) criminogenic need items. There are two particular advantages to including dynamic risk items in an offender recidivism prediction. First, as the situation and conditions of the offender change over time, an accurate reassessment will reflect these changes in risk that are occurring either naturally or by means of some kind of treatment or intervention. Secondly, dynamic criminogenic needs are, by definition, the characteristics of an individual, which, when changed, translate to changes

in offender recidivism, thus giving the probation officer or other correctional worker or service provider direction as to how to facilitate the rehabilitation of the offender.

Design and Content

Andrews's goal was to develop a wide array of predictor items that could capture the diversity of risk factors that contribute to offender recidivism. To achieve that goal, he conducted a thorough review of offender documents on file and consulted with collateral individuals who could provide insight about offenders. Andrews then realized that more detailed information than what was routinely available in offender files was required so he developed an interview guide to unearth some of the more nuanced aspects of offender risk. He also worked with data sets of probationers and their outcomes that were provided by the Ontario Ministry of Correctional Services. Items were added and deleted in a series of revisions in an effort to capture not only the best combination of predictors but also ones that could be used to guide probation officers' supervision of their clients. Probation officers and their managers were also consulted in the choice of items and the design of the instrument. The result was the Level of Supervision Inventory VI.

The LSI-VI consisted of 58 items that were grouped into 11 sections. These sections and the number of items in each section (in brackets) included the following: Criminal History (10), Education/Employment (10), Financial (2), Family/Marital (3), Accommodation (3), Leisure/Recreation (2), Companions (5), Alcohol/Drug Problems (9), Emotional/Personal (5), Probation/Parole Conditions (4), and Attitudes/Orientation (4). It is readily apparent that some domains included many more items than others. As each item counted as a single point, varying the number of items in a domain allowed Andrews to weight the different domains in accordance with their perceived importance as determined by the research at the time. Specifically, criminal history, education and employment, and alcohol and drug problems were perceived as being most strongly related to criminal recidivism, while financial issues, leisure and recreation activities, and accommodation were relegated to minor risk domains. The total score was the sum of all items

endorsed and was used to determine a level of supervision for the probationer.

But the LSI-VI also included a scoring quirk. Realizing that many of the criminogenic need factors existed on a continuum, Andrews established a 0–3 rating scale to describe the degree to which a *positive* attribute, or strength, is present. For example, a maximum rating of 3 on the Employment item, Participation/Performance, occurs when the offender expresses a strong interest in job, takes pride in abilities/performance, has reliable attendance, is willing to work overtime, and wants to stay in the same line of work. A minimum rating of 0 occurs when the offender says he or she hates work, can't perform well, has unreliable attendance, and is often late. This finer level of detailed scoring can be used to track minor adjustments, improvement or deterioration, and can assist with the case management of the offender. However, these items are reduced to a binary (0 or 1 = 1 and 2 or 3 = 0) for the purpose of calculating the total risk/need score. This format has been retained in all subsequent versions of the LSI.

The preceding description of the Employment item, Participation/Performance, illustrates three important aspects of the LSI items. First, it taps into dynamic aspects of offender risk that exist along a continuum and are subject to change, sometimes rather quickly. Second, items are true to social learning theory and the PIC-R principles in that they are based on the *eligibility* for different kinds of rewards and punishments for prosocial and antisocial behavior in the offender's environment. (Note that the next 2 items in the LSI-VI capture the nature of the offender's relationship with peers and with authority figures in the workplace.) Third, the LSI-VI considers both the presence of risk items and strengths (i.e., protective items) with the absence of a strength being scored as 1. Critics of the LSI often fail to appreciate this means of considering offender strengths.

Another feature introduced in the LSI-VI (and maintained through all subsequent versions of the LSI) included an opportunity for the assessor, typically a probation officer, to *override* the score-derived level of supervision. A text box was included for assessors to note both positive and negative circumstances that may not have been

given sufficient attention in the established LSI-VI items. Pending charges, extreme violence, or particularly notorious actions might be used to elevate the degree of supervision, while positive circumstances might include prosocial supportive factors that would enable the assessor to reduce the level of supervision suggested by the LSI-VI score.

Andrews then wrestled with the number of risk levels into which the raw score could be collapsed, both for statistical analysis and for correctional workers to describe the degree of risk presented by an offender. An initial scheme created four levels of risk: 0–7, 8–11, 12–23, and 24–58. But this allocation was quickly reduced to three risk groups to correspond with the three traditional levels of supervision in community corrections (i.e., minimum, medium, and maximum). This was achieved by combining the two highest risk groups in part because only about 4% of the probationers in the early research scored over 24 in spite of the fact that this was a 58-point scale. Subsequent versions of the LSI have used four and even five levels of risk.

Initial Research

Research on the LSI looked promising right from the start. Beginning in the early 1980s, two important reports to the Ontario government summarized an impressive list of results. To begin with, agreement between raters was considered high and was generally consistent with probation officer judgments pertaining to the required supervision of offenders at the outset of their probation and later, midway through the supervision process, both in the order of 90% agreement. Moreover, LSI scores were consistent with the actual number of supervision hours as documented in case records. Low LSI scores corresponded with probationers who were granted an early case closure, while high LSI scores corresponded with in-program recidivism (i.e., charges and reconvictions), multiple reconvictions, reincarceration, and self-reported criminal behavior. The LSI also predicted postprobation recidivism over a 3-year period, with increased accuracy as follow-up time increased. Working in a detention facility, Bonta found that the LSI predicted failure among prisoners who were referred to a halfway house.

Moreover, a number of LSI sections were related to other self-reported measures of related constructs. For example, criminal history was related to self-reported crime, education/employment was related to inadequacy–immaturity, alcohol/drugs was related to self-reported drug offenses, and personal/emotional was related to sensation seeking and negatively to self-control.

The second review not only replicated many of the original findings but also expanded on them. LSI subsection scores correlated with a host of well-established paper-and-pencil psychometric measures of related constructs. Probation intake LSIs were strongly correlated with in-program recidivism. LSI scores correlated with both official and self-reported (i.e., undetected) crime. Importantly, probationer progress signaled changes in their outcome in that retest LSIs were more predictive of recidivism than intake LSIs, and changes on an LSI progress assessment were associated with corresponding changes in the chances of recidivism. The allocation of more intensive services to high-risk offenders was rewarded with disproportionately lower recidivism rates than when intensive services were allocated to low-risk offenders.

In Australia, when LSIs were conducted in conjunction, but not submitted, with presentence reports, the presentence LSI was associated with the disposition of the court: Those who received fines or acquittals received the lowest scores, followed by short-term probation, long-term probation, and finally a prison term. These results led to an obvious question: Are less serious offenders at lower risk or are offenders who are lower risk more likely to get less severe sentences? This and other findings have generated continued discussions about conducting an LSI prior to sentencing, or even conviction, and the role of the LSI in the sentencing process.

Final Thoughts

By the end of the 1980s, the LSI had established a solid research-based, respected position in Ontario and garnered a selective following beyond. Its reputation was based on the following:

- (1) It provided a standardized record to guide the discretionary controls and services offered by the correctional agency.

- (2) It corresponded with actual levels of supervision that were being applied at the time and correlated with correctional outcomes to an acceptable degree of accuracy.
- (3) It demonstrated what became known as the risk principle by showing that augmented services were *wasted* on low-risk offenders but reduced recidivism when used on high-risk offenders.
- (4) The LSI captured numerous empirically demonstrated factors related to criminal behavior.
- (5) Its demonstration that assessments of change corresponded to changes in outcome encouraged more efficient and effective allocation of correctional resources.
- (6) Finally, these studies offered robust evidence for the predictive validity of the LSI across a wide range of circumstances, including various types of offenders, several probation offices, various measures of offender outcome, and in different criminal justice contexts, including court, probation, and prison.

LEVEL OF SERVICE INVENTORY– REVISED (LSI-R)

The LSI-R is a risk assessment instrument designed to identify adult offenders' likelihood of reoffending and is widely used in corrections. The instrument has been built on extensive empirical evidence about offender risk factors and pilot-tested extensively prior to its formal release. The LSI-R is part of a new, third generation of offender risk instruments known as risk/need assessments, because its items include a balance of historical and demographic static risk factors and an array of dynamic criminogenic need factors. This entry describes the LSI-R, its place among LSI instruments, its content and widespread use, its training protocol, and its validity.

Background of the LSI-R

The LSI-R is an adaptation of Donald Andrews's original LSI Level of Supervision Inventory, (LSI-VI). In fact, the LSI was administered and researched for more than a decade before its release as the LSI-R. By the time the LSI-R was published in 1995, there were at least 25 research papers on the LSI-VI that established its psychometric properties, including its inter-rater and test-retest reliability, internal consistency, construct validity (i.e., the extent that it correlated with other measures of constructs such as propensity for rule violation), and its predictive validity (i.e., its correlation with subsequent recidivism and other antisocial behavior such as rule violation). However, with the exception of a few studies, mostly with Canadian federal offenders, this research was conducted on offenders who were on probation or in provincial facilities in Ontario, Canada. Regardless, the LSI-VI served, in essence, as a pilot instrument affording many opportunities for risk/need assessment

research prior to the formal release of the LSI-R by Andrews and his colleague, James Bonta, in 1995.

Content and Organization of the LSI-R

The LSI-R is very similar to the LSI-VI in content. It includes the same 54 items grouped into the same 10 domains or sections: Criminal History (10), Education/Employment (10), Financial (2), Family/Marital (3), Accommodation (3), Leisure/Recreation (2), Companions (5), Alcohol/Drug Problems (9), Emotional/Personal (5), and Attitudes/Orientation (4). (The LSI-VI test option to include write-in items listing specific conditions for probation or parole has been eliminated.) The LSI-R is available in a paper-and-pencil format on a carbon paper QuickScore Form that allows for expedient manual scoring. The publisher, Multi-Health Systems, also offers a Windows-based computer program that generates a profile report, a comparative report, and a group report.

Norms were developed for male and female offenders, listing the percentile ranking of offenders throughout the range of possible scores on the instrument. In addition, five risk levels were created for male inmates with labels and 1-year recidivism rates (return to custody) as follows: high (72%), medium/high (57.3%), moderate (48.1%), low/moderate (31.1%), and low (11.7%). The authors also suggested guidelines for the classification of offenders in various contexts including guidelines for the amount of supervision of probationers (minimum, medium, and maximum); placement to a halfway house (appropriate, appropriate with close supervision, and inappropriate); and inmate classification to security level, with separate cutoff scores for recommendations for male and female prisoners.

An easily overlooked but important symbolic difference between the LSI-IV and LSI-R was its change in name. With the development of the original LSI, the objective was to determine the *level of supervision* that should be afforded to each probationer. But that was seen as limiting since, as a dynamic risk/need assessment tool, the LSI-R offered direction for a full range of services to offenders by identifying an offender's particular criminogenic needs. Moreover, as research was developing on the importance of having a full

range of services to offer offenders in the community, the function of probation officers was evolving from traditional supervision to direct service provision and brokering or advocating for services to address offenders' specific criminogenic needs. Hence the original term, *level of supervision*, was replaced by the more inclusive *level of service* terminology.

Rise in the Popularity of the LSI-R

The commercial release of the LSI-R brought the tool to criminal justice agencies (primarily corrections), academics, and clinicians worldwide. Growing use of the LSI-R occurred both geographically and across multiple correctional contexts. This included prisons where it was introduced to predict recidivism, to select offenders for release, and to classify offenders according to security level. Some agencies also began to conduct LSI-Rs as part of the presentence investigation. Although the instrument was never designed to offer advice to the court about the severity of the sentence, it can be used to inform conditions of the sentence, including orders for treatment or programming or behavioral conditions (e.g., the offender would be instructed not to consume alcohol or to associate with certain individuals).

Because of its growing popularity in large correctional agencies, some with tens of thousands of offenders to assess per year, and its lengthy time to complete, often a number of hours for an offender interview, a thorough review of various documents, and collateral checks, a short version of the LSI-R, the LSI-R: Screening Version, was released in 1998. It consists of 8 items and can be used to determine which offenders are most likely to be high risk and therefore deserve a complete LSI-R assessment.

The decade following the publication of the LSI-R saw a dramatic increase in its use in the field and in research pertaining primarily to assessing its predictive validity with respect to recidivism. By 2010, LSI assessors logged more than 1 million administrations of the LSI-R, its youth version/Case Management Inventory (YLS/CMI), and its successor (LS/CMI), in a single year. But, this popularity also led to new concerns. Any risk assessment tool, regardless of its inherent value, is only as good as the assessor who administers it.

LSI-R Training

In order to accommodate the LSI-R's growth and popularity and at the same time protect its integrity, standard training packages were developed and a system of user certification was created. A "train the trainer" approach was introduced to address the sizable, widespread demand for training from North America, Europe, and more recently, Pacific Rim countries.

To begin, the authors built a training curriculum that included theory and research on criminal behavior, detailed instructions on administration of the tool, practice exercises that increased in complexity, and testing of both the content and the administration of the instrument. Typically, trainers are handpicked members of a correctional organization, who demonstrate a deep understanding of and appreciation for the LSI-R and its underpinnings, as well as having other kinds of social skills that enable them to work effectively with their colleagues. Upon successful completion of training, trainers are certified by the publisher as LSI-R trainers and mandated to offer high-quality training to field staff.

A mechanism was established to create *master trainers*, individuals who were authorized to train trainers to give LSI-R training. Most master trainers are experts in the field, typically having a combination of research experience, professional training, expertise in the field of corrections, and experience administering LSI-Rs and conducting LSI-R training. Master trainers also include criminal justice professionals who do LSI user and trainer training as part of their own practice or consulting service. With the proliferation of the LSI-R, it quickly became apparent that having master trainers was essential to meet the need for trainers in large correctional agencies, some of which have hundreds of probation officers.

Research on the LSI-R

Upon its publication, the LSI-R generated a great deal of offender risk/need research by academics and correctional agencies in Canada, the United States, and beyond. Although it was succeeded by a subsequent version (LS/CMI) in 2004, in 2013, it was the most widely researched version of the LSI, with more than 50 predictive validity studies.

These studies examined the capacity of the instrument to predict antisocial behavior. General recidivism was the most common outcome criterion but others included violent recidivism and failure on supervision in various community contexts including probation, parole, and community residential settings or halfway houses.

The LSI-R research firmly established the instrument's predictive validity. It did so with various offender groups, including women and ethnic minorities, in various jurisdictions, particularly Canada and the United States, in custody and community. However, there remains some debate about the *equivalence* of the LSI-R across gender, race, ethnicity, and jurisdiction, particularly countries. Andrews's initial position was that risk factors, including criminal history, criminal attitudes, criminal associates, and lack of opportunity through education and employment, are universal risk factors that merit consideration in the assessment of any potential offender. Some critiques have suggested that these factors might not be equally applicable across all demographic groups and national borders but have differing levels of importance or *weighting*, while others have suggested that factors related to social location, including gender, race, and poverty, lead to other delinquent pathways that are not captured in the LSI-R. This could lead to bias in the administration and use of LSI-R. Although some individual studies have shown disparities along these dimensions, Mark Olver's comprehensive meta-analysis of the Level of Service Scales revealed consistent predictive validities of total score by race and gender but not by nationality (i.e., lower in United States) and ethnicity (i.e., lower among Hispanics).

As a third generation risk assessment tool, one of the research objectives of the LSI-R was to illustrate its dynamic predictive validity. This was achieved by demonstrating the improvement of latter reassessments of offenders in terms of their statistical relationship with recidivism. A popular way of examining LSI-R reassessments was to compare recidivism rates of offenders who went either from low risk during the initial assessment to high risk upon reassessment or vice versa, from high risk to low risk. To be clear, changes of this magnitude in the 8- to 12-month intervals used in these studies are dramatic, the former being a recipe for disaster and the latter an indication of

considerable optimism. Follow-up analyses bore out these prognostications. In five studies, offenders who went from high risk to low risk had, on average, a 37% lower recidivism rate than those who remained at high risk. Conversely, those who went from low risk to high risk had, on average, a 26% higher recidivism rate than those who stayed at low risk.

With the emergence of other offender risk assessment tools, there was a noteworthy sparring match in the early 2000s between the LSI and Robert Hare's Psychopathy Checklist-Revised. The Psychopathy Checklist-Revised had emerged at about the same time as the LSI-R, but it was formally designed as a measure of offender psychopathy and not as a risk assessment instrument, although it had been applied as such both clinically and in research. Currently, the consensus is that there is little, if any, difference between these two instruments, and a number of other scales, in terms of statistically derived measures of predictive validity. However, they do have numerous other differences, such as their theoretical orientation and applicability in a clinical and programmatic purpose. The current wisdom is that these other characteristics should guide the choice of risk assessment instruments.

Final Thoughts

The LSI-R was crafted as a risk/need offender assessment instrument both to predict offender recidivism and to guide planning and programming with the offender. There is no doubt that it accomplishes the first goal. The extent to which it has achieved its second goal is less clear. Studies in a number of jurisdictions have demonstrated that the tool is not used to its full capacity when it comes to case planning and intervention. In fact, case management and intervention may be based more heavily on the court's recommendations or conditions than the criminogenic needs identified on an LSI-R. This is not surprising for two reasons: one, the authority wielded, justifiably, by the judge; two, the fact that there is nothing inherent in the LSI-R that *explicitly* guides or directs case planning and intervention. This led to another (fourth) generation of offender risk assessment instruments, one that was characterized by the LS/CMI. Nonetheless, the LSI-R remains one of the

most widely used offender risk/need assessment tools throughout the world.

LEVEL OF SERVICE INVENTORY-SELF-REPORT (LSI-SR)

The Level of Service Inventory-Self-Report (LSI-SR) is a pencil-and-paper, self-report version of the LSI (i.e., a risk assessment instrument that was designed to identify adult offenders' likelihood of reoffending) and its subsequently published version, the LSI-R. Originally known simply as the Self-Report Inventory and sometimes referred to as the *LSI-R:SR*, the LSI-SR was

developed by Michelle Motiuk in 1988. The instrument adhered to the principles and content of the original LSI, but it allowed for its completion by the offender, as opposed to a correctional professional, such as a probation officer or psychologist. The LSI-SR was developed in part because of the time and resources that correctional agencies had to commit in order to conduct a single LSI. Since it was common to ask offenders to complete other psychological assessment instruments, such as the Minnesota Multiphasic Personality Inventory, in a self-report, but supervised, manner, it was reasoned that the same format could work with an offender risk/need assessment. This entry describes the items on the LSI-SR, the empirical evidence for its concurrent and predictive validity, and its place among offender management tools.

Items

The LSI-SR consists of 78 items in a questionnaire format. Most of the items are answered in a yes–no manner, although some questions ask for a specific number, and there is one 4-point, Likert-type scale item. Items are grouped in the same 10 domains found in the original LSI and the LSI-R. They include the following: 9 criminal history items (e.g., “Have you ever been arrested as a juvenile?”); 7 education/employment items (e.g., “Have you ever been fired from a job?”); 4 financial items (e.g., “I have been on welfare or unemployment insurance.”); 9 family/marital items (e.g., “Both parents are deceased.”); 5 accommodation items (e.g., “I have no fixed address.”); 5 leisure/recreation items (e.g., “During my spare time, I spend a lot of time in criminal activity or planning a job.”); 5 companion-related items (e.g., “Not counting relatives, how many people do you know have a criminal record or have been involved in crime?”); 22 alcohol/drug-related items (e.g., “When I drink I tend to get in trouble with the law.”); 6 emotional/personal items (e.g., “Have you ever attempted suicide?”); and 6 attitude/orientation items (e.g., “All laws should be strictly obeyed.”). Another self-report offender risk assessment instrument that includes many of the same domains as the LSI-SR is the Self-Appraisal Questionnaire.

Validity

Motiuk’s original research yielded encouraging results for the validity of the LSI-SR. The measure was highly correlated with a traditionally conducted, interview-based LSI assessment ($r = .78$) on a sample of incarcerated adult, male offenders. The 10 domains of the LSI-SR were highly correlated with the corresponding interview-based domains of the LSI, with the exception of the financial and attitude/orientation sections. Moreover, six of the individual sections of the LSI-SR were highly correlated with independent self-report measures of constructs that the LSI-SR sections were designed to capture ($r = .33$ to $.60$). These included scholastic maladjustment, family dissention, urge to use alcohol/drugs, identification with criminal others, attitudes toward the courts, and anxiety. In terms of predictive validity, the LSI-SR correlated modestly with subsequent prison misconduct, parole violations, and reincarceration ($r = .17$ to $.29$). There are a couple of important caveats that should be noted with respect to these initial findings regarding the LSI-SR. First, offenders were screened for their reading proficiency on the Wide Range Achievement Test before being admitted to the study. Using a Grade 6 criterion, 17% of the volunteer prisoners were excluded. Therefore, the validity findings of this study would be applicable to a similarly selected group of literate offenders. Second, the study did not include any assessment of social desirability, faking, or other kinds of participant response set. Hence, the convergent validity correlations between the sections of the self-report LSI-SR and their corresponding alternative self-report measures may be inflated by virtue of their common method of data collection (i.e., self-report). For example, offenders who minimize their antisocial attitudes on the attitude section of the LSI-SR would likely also do so on the independent measurement of their tolerance for law violation.

The subsequent empirical evidence for the predictive validity of the LSI-R:SV is limited but positive. Another study has demonstrated good predictive validity of the LSI-SR with incarcerated, adult women offenders ($r = .30$). A meta-analysis by Mark Olver and colleagues reported on five LSI-SR studies having a mean correlation of $.38$ with general recidivism and on two studies with a mean correlation of $.28$ with violent recidivism.

Final Thoughts

The LSI-SR has not seen the same growth that other versions of the LSI have experienced. This is quite likely because of the hesitation of correctional professionals to use the results of an assessment that is based solely on the offender's own input when it comes to making critical decisions about the offender's management. These decisions include security level in custody, release from custody, the determination of supervision intensity in the community, and the type and intensity of rehabilitation programming to which the offender might be referred. These are very different contexts from a research setting where there are no particular consequences for answering the LSI-SR questions one way or another. Nonetheless, it remains an interesting research tool, as are other self-report measures of antisocial constructs including psychopathy, antisocial personality, and criminal thinking, all of which are correlated with the LSI-SR.

LEVEL OF SERVICE/CASE MANAGEMENT INVENTORY (LS/CMI)

The LS/CMI is one of the Level of Service Inventory (LSI) instruments. It is an example of a *fourth generation* offender risk/need assessment scale and is distinguished from previous generation instruments by the fact that it was not only designed to predict offender recidivism but also includes a built-in case management component that translates the need portion of the assessment to an active intervention plan for offender supervision, treatment, and programming. Like the LSI-Revised (LSI-R), the LS/CMI was pilot-tested on a large scale for almost a decade prior to its general release. This entry describes the origins of the LS/CMI, places it historically in the sequence of LSI instruments, itemizes the differences between it and its predecessors, and summarizes the research that it has generated.

History and Evolution

While the LSI-R was enjoying widespread success and was being implemented in Canada, the United States, and numerous European and Asian countries in the mid-1990s, it became evident to the authors, researchers, administrators, and end users that it could be expanded. Specifically, there was a growing sense that the scope of the assessment should be broadened and its linkage to offender supervision and intervention should be strengthened.

Consequently, Donald Andrews, along with James Bonta and Stephen Wormith, began a systematic review of the research and practical experience that had accumulated by that time. There was already extensive, system-wide experience

with the LSI-VI (later known as the *LSI-R*) in Ontario, where correctional authorities were considering extending its use into its provincial prisons. They analyzed LSI assessment and recidivism data provided by the Ontario government. They also reviewed the early and rather crude, by today's standards, meta-analyses on offender's risk factors and recidivism. This review coincided with the emergence of the *Central Eight* domains of offender's risk/need factors and helped to reorganize and reformat the next version of the LSI.

The authors also consulted with LSI assessors, primarily probation officers and psychologists, about their clinical experiences with the offenders they had assessed. They asked what more should the LSI provide to users in the field. They met with various levels of correctional officials, from senior administrators responsible for corporate policy to staff supervisors in the field, professional associations, and the provincial parole board. Routinely, they asked, what more would the various stakeholder groups like to see in the instrument to improve it, to ease its use, and to increase its value to the organization.

In 1995, the LSI: Ontario Revision (LSI-OR) was introduced into Ontario's provincial correctional services, in both its probation offices and its correctional institutions. Then, in 2004, the LS/CMI was released for more general use by correctional agencies around the world. It included organizational and stylistic modifications from the original LSI-OR, but none of the actual items in the core risk/need assessment portion were changed. In other words, as was the case with the LSI-VI and the *LSI-R*, the LSI-OR served as a thoroughly monitored and researched precursor to the LS/CMI.

Structure and Organization

Research and consultation led to nine critical enhancements to the *LSI-R* that are found in the LS/CMI. The first is a reduction of items from 53 to 43 that were grouped into eight, instead of the original 10, domains or subscales in the general risk/need section of the LS/CMI. These eight domains represent the *Central Eight* risk factors for offender recidivism that have emerged from various meta-analyses. They include criminal history, employment/education, leisure/recreation,

family/marital, companions, criminal attitudes, substance abuse, and antisocial pattern. The accommodation and financial subscales from *LSI-R* were eliminated as were some redundant items. The emotional/personal section in the *LSI-R* was changed to a new domain called *antisocial pattern*. The antisocial pattern domain is somewhat different than the other subsections. It is also reminiscent of Robert Hare's *criminal versatility* in the Psychopathy Checklist-Revised but is not limited to criminal behavior per se, but a general lifestyle, including antisocial thoughts, actions, and personality. As such, many of the concepts that are captured in its items come from the other *Central Eight* domains in the general risk/need section of the LS/CMI.

The redesign of the general risk/need factor section enabled a second new feature of the LS/CMI. Greater attention is given to the eight subsections of the LS/CMI than was ever afforded to the 10 categories of the *LSI-R*. For example, the subsections are scored and graphed in the same way that one plots a profile of subscale scores on many of the standard measures of intelligence and personality. The resulting graph allows the practitioner to visually inspect the results of the general risk/need assessment along the *Central Eight* risk factors and to make the links with case management, particularly programming and supervision, more easily.

A third new aspect of the LS/CMI is that the number of risk factors was increased to five (*very low*, *low*, *medium*, *high*, and *very high*) from the three or four risk levels in various representations of the *LSI-R*. It should be noted that the number of risk levels in any scale or instrument is decided arbitrarily by the developer or the agency using the instrument. The number of risk levels of a risk scale usually depends on the developers' confidence in the instrument's ability to discriminate between groups on the basis of small differences in scores. An accurate scheme with few levels of risk classification essentially loses some of its precision by collapsing offenders into larger categories. Since numerous LSI studies have produced generally a linear relationship between the LSI score and probability of recidivism, a five-level risk scheme was used so that the decision maker or case manager would be working with a more accurate description of the offender in terms of his

or her risk to reoffend. The five levels of risk were also applied to the eight risk/need domains, thus enabling the graphic risk/need profile described earlier.

A fourth enhancement found in the LS/CMI was the introduction of offender strengths. One of the criticisms of traditional offender risk assessment instruments, including the LSI-R, was that they focus exclusively on risk, or the negative characteristics demonstrated by the offender, and ignore any positive attributes that he or she might present. The concept of strengths, characteristics that might serve as protective factors from a lifestyle of criminality, was introduced. Any of the risk/need domains may be declared as a strength if the assessor believes that a particular domain represents an area in which correctional workers could use it when taking on some of the more problematic need areas in the offender's profile or could focus on it to build offender motivation, confidence, and rapport with the offender. The presence of strengths may also be used to adjust the offender's overall risk rating if it is believed that a particular strength may mitigate a corresponding risk/need, such as a strong, prosocial parental role model neutralizing criminal acquaintances. These aspects of the LS/CMI are often overlooked by critics who characterize it strictly as a risk/need assessment.

A fifth enhancement of the LS/CMI is that it adds a supplementary list of specific risk/need items that might be considered in an offender's overall rating and profile. This addition was a result of input from clinical professionals and other practitioners who were concerned about specific features of an offender that might not be captured in the Central Eight risk/need domains and their 43 items. The specific risk/need factors section consisted of 21 items grouped into two subsections, personal problems with criminogenic potential and history of perpetration. Many of these items, particularly in the second subsection, were designed to capture items that might relate to risk of violent recidivism including sexual recidivism. These items are not scored or added quantitatively. Rather, they serve as a checklist of possible problems that should be considered, both in assessing or adjusting risk and in case planning. Nonetheless, studies have demonstrated that the number of items endorsed in this section is

positively correlated with recidivism, including violent recidivism.

A sixth enhancement relates to the manner by which assessors may override the original risk level of an offender (i.e., that which is derived directly from the general risk/need assessment score). At the end of every LS/CMI assessment, the assessor is asked specifically whether he or she elects to exercise a clinical or administrative override. This feature was added to the LS/CMI in large part to accommodate the concerns of practitioners. It also routinizes the override, a concept that is related to one of Andrews's basic principles of effective correctional treatment, namely *professional discretion*. Specifically, assessors are asked whether there are sufficient grounds to modify the score-based risk level. Factors to be considered in making such a determination are the presence of strengths (to lower risk) and supplementary risk factors (to increase risk). An administrative override was also allowed to accommodate correctional agencies that require certain offenders to be classified in a specific manner, as a matter of policy. The value of the override, however, at least empirically, has not been demonstrated.

A seventh enhancement of the LS/CMI introduced other clinical issues to the traditional risk/need assessment protocol. These include social, health, and mental health needs of the offender. This section extends the LS/CMI beyond its traditional risk/need function to a more comprehensive offender assessment. Its items are also considered for professional and ethical reasons. It is perhaps a little ironic that, after a decade of trying to convince professionals to consider criminogenic needs (the Central Eight) as opposed to traditional clinical issues relating to client well-being, the LS/CMI brings the assessor back to these traditional social- and health-related matters (e.g., homelessness, suicidal, HIV, self-esteem, and victimization). However, to call the items in this section *noncriminogenic* appears to be erroneous as studies that have examined this section's score have found a modest positive correlation with recidivism.

Related to the previous item, the eighth enhancement to the LS/CMI introduced the concept of specific responsivity into the assessment process. The responsivity principle is one of three key aspects in the Risk-Need-Responsivity (RNR) model of effective intervention with offenders.

Specific responsivity pertains to particular characteristics of the offender that should be considered when planning and delivering case management practices (supervision and intervention) to an individual offender. Generally, they include demographic characteristics (e.g., age, gender, and race or ethnicity), personality and mental health attributes (e.g., anxiety, antisocial characteristics, mental disorder, and motivation), and cognitive attributes (e.g., intellect and various kinds of disability). The LS/CMI asks assessors to document these characteristics and encourages case managers and other users of the assessment to attend to them in the delivery of services to the offender. Thus, by considering specific responsivity characteristics of the offender, along with offender strengths and other, noncriminogenic needs, the LS/CMI extends the assessment beyond the traditional offender risk/need assessment protocol.

To accommodate the diversity of contexts to which the LS/CMI might be applied, the ninth enhancement to the LS/CMI constituted a new section devoted to institution (jail and prison) behavior. Separate subsections capture information pertaining to both previous incarcerations and the current term in custody. Items focus on security classification, disciplinary incidents, and special accommodation needs, such as segregation. Because of the inclusion of these institutional items, the LS/CMI is now being used as part of an inmate classification and case management system in some jurisdictions.

Addition of Case Management

The final enhancement to the LS/CMI entails a concrete effort to link the offender risk/need assessment to offender case management, hence the CM component of LS/CMI. The combination of a risk/need assessment and a case management procedure in the same document was triggered by consultation with experts in the field and by some early empirical investigations that revealed a disconnect or, at best, a weak connection between risk/need assessment and offender case management that fell short of expectations. In retrospect, it was apparent that instructing correctional practitioners to “just do it!” was unrealistic. An important study that demonstrated a need for risk assessment to be more directly related to offender

planning and supervision was conducted by Bonta with probationers in Manitoba, Canada. Bonta and colleagues revealed that the probation officers’ supervision conformed much more strongly to the formal conditions of the probation order than the offender’s risk/need assessment. Similar findings were unearthed in Texas, where directions from an instrument, the Client Management Classification system, were ignored more often than they were followed to the detriment of offender’s success in the community.

Consequently, the LS/CMI added three more sections devoted to case management of the offender: (1) the case management plan, wherein interventions were developed in the context of the offender’s criminogenic needs, noncriminogenic needs, and responsivity characteristics; (2) the progress record, wherein positive and negative changes in the status of the offender are documented in the context of their LS/CMI assessment profile; and (3) a discharge summary, which reflects on the offender’s status upon release vis-à-vis his or her assessment upon entry. Because numerous correctional organizations use their own internal case management record, a truncated version of the LS/CMI, the LS/RNR, which simply omits the three case management sections of the LS/CMI, was published in 2008.

In sum, the LS/CMI is a more comprehensive assessment than the LSI-R and other third generation risk/need assessment tools and is more directly linked to the subsequent and ongoing case management (supervision and service delivery) of the offender. As such, the LS/CMI was deemed a fourth generation offender risk assessment tool.

Research

As is the case with other versions of the LSI, a substantial body of research has been produced documenting the predictive validity of the LS/CMI with various types of offenders, in various legal contexts, and in various jurisdictions. Although some differences in the magnitude of the relationship between LS/CMI score and recidivism differ along these dimensions, Canadian LS/CMI studies generate a stronger LS/CMI relationship with recidivism than studies conducted in other jurisdictions (outside North America, followed by the United States). In addition, some, but not all,

studies have suggested that there are differences by gender and race. Nonetheless, the overall robustness of the LS/CMI is well established. This is illustrated in a meta-analysis that summarized 30 years of LSI research. Examining 151 offender samples, Mark Olver and colleagues found that the LS/CMI and LSI-OR tend to perform as well or better than its LSI predecessors.

The Future of the LS/CMI

The LS/CMI has emerged among a growing number of offender risk assessment tools as one of the most widely used instruments, worldwide, slowly surpassing its predecessor, the LSI-R. In designing the LS/CMI as an assessment tool that includes both traditional risk/need components and other noncriminogenic needs and responsivity features and then combines it with offender case management, it was anticipated that it would *force* correctional workers and their agencies to apply the RNR principles on offenders, one by one. The link between risk/need assessment and RNR-based intervention may be further strengthened in automated versions of the LS/CMI, as implemented, for example, in Oregon. Moreover, LS/CMI validation research continues across multiple types of offenders, including driving while impaired and child pornography offenders, and in a wide range of jurisdictions that extend beyond North America and Europe to countries such as Chile, Singapore, Hong Kong, China, and Pakistan. Yet, empirical demonstrations of its capacity to change the postassessment supervision and counseling practices of correctional workers remain few.

LIE DETECTION

In a forensic context, a lie is defined as a sender transmitting a message with the deliberate intention of misleading the receiver to cultivate a false

belief or conclusion. The important element of this phenomenon is that the sender is cognizant of his or her intent to distort the truth, and the expectation is that the receiver does not anticipate or detect this. In criminal investigations, a primary aim of law enforcement agents and expert witnesses is to reliably and accurately distinguish truths from lies. This entry reviews the tools developed to aid the detection of lies, explores lie detection accuracy, and examines stakes and response biases in lie detection.

Tools That Aid Deception Detection

Verbal

Several speech analysis tools have been developed to aid experts in distinguishing truthful from fabricated accounts of events in the forensic setting. These include the Statement Validity Assessment, which is a credibility assessment tool used for accounts relating to interviewees' reporting of events and experiences. Criteria-Based Content Analysis, a component of Statement Validity Assessment, can be used by interviewers to focus on features considered to correspond with truthful accounts. Scientific Content Analysis is another credibility assessment tool, which helps appraise both quality and content of information given by interviewees. While accuracy rates using Criteria-Based Content Analysis in laboratory settings (i.e., accurately categorizing a truthful account as truthful and a deceptive account as deceptive) are found to be higher than chance level for detecting truth and lies, these procedures are generally not satisfactorily admissible as key evidence in criminal court cases.

Physiological

Physiological tools developed to aid deception detection have had varying degrees of success. Polygraph tests indirectly infer deception through the examination of physiological reactions in relation to a series of structured yet unstandardized questions. The autonomic arousals typically evaluated are respiration, sweating of the fingers, and blood pressure. The Comparison Question Test is one type of a polygraph procedure universally used in criminal investigations. It compares responses of relevant questions specific to the crime (e.g., "On June 21, did you stab your

husband?") with control questions not specifically related to the crime and which are generally broader in scope (e.g., "Have you ever hurt someone who trusted you?"). The underlying assumption of this test is that a truth teller will indicate a higher level of arousal for control questions in contrast to relevant ones since relevant questions inquire into a crime they are not culpable of. In contrast, a liar is anticipated to reveal higher arousal for relevant questions since these questions correspond to a more severe and current threat. There is insufficient evidence demonstrating that polygraph procedures are highly accurate in detecting deception, due to the underlying theoretical assumptions of the tests. Empirically, it cannot be verified that distinctive physiological responses diagnostically indicate that deception is present. Consequently, polygraphs are used by police or attorneys as a basis for interrogations and risk assessments rather than being presented as evidence of deception in criminal courts.

An equally controversial advancement in physiological procedures to aid lie detection is functional magnetic resonance imaging. Studies have shown potential in this technology, which reveals that certain regions of the brains are more engaged when an individual is lying compared to when he or she is telling the truth. The same cannot be determined when individuals are telling the truth, demonstrating that lying is more cognitively demanding than truth telling. Yet, these findings cannot systematically verify the underlying assumption that an individual is lying when certain regions consistently activate during a task, even across several trials. Any subsequent results displaying neural patterns can only be considered as correlational and not causal with associated cognitive activity or behavior of deception requiring additional substantiation. In its present form, the functional magnetic resonance imaging procedure fails to satisfy the reliability prong of the *Daubert* standard set by the U.S. Supreme Court, as well as its precedent, the *Frye* standard. Research has also cautioned that the accuracy of detecting false positives and true negatives, while higher than that of the polygraph procedure, may see to a dramatic decrease in higher stakes cases due to noncompliance and countermeasures that can be employed by suspects. Lie detection reports grounded on functional magnetic resonance imaging results are

yet to be endorsed as admissible evidence into trial courts (i.e., *United States v. Semrau*, 2012).

Lie Detection Accuracy

Lie detection accuracy is usually quantified by the number of correct assessments relative to the total number of assessments made by receivers. Deception detection research has revealed that individuals are generally poor lie detectors, no better than chance.

Earlier explanations as to why we are poor include that we often draw invalid cues of deception from accounts given, such as the Othello error. Examples of this error include nervousness as a sign of lying, liars always do not give rich detail in their accounts, and eye-gaze aversion is always an indication of lying. Another prevalent belief is that nonverbal cues are more diagnostic and reliable than verbal ones, due to the belief that liars are more capable of regulating their verbal behaviors compared to their nonverbal ones.

For a while, it was believed that the two main reasons human judges are poor in detecting deception is because people tend to use undiagnostic cues and because there is a lack of diagnostic cues when it comes to deception. Conversely, it has been found that humans are poor judges of deception due primarily to the weaknesses of the behavioral cues themselves. In reality, then, people seldom rely on invalid cues.

The ability to detect lies is also subject to individual differences. An individual's ability to detect lies and truths is not associated with confidence levels but with other characteristics (e.g., personality traits). Some groups of individuals also perform better than others. For instance, the Central Intelligence Agency's federal officers, county sheriffs, and clinical psychologists were able to accurately judge lies and truths at a rate significantly higher than chance level. In addition to the issue of observer lie detection ability, certain senders simply appear more credible than other individuals whether or not they are telling the truth—a term coined *sender detectability*.

Stakes Do Not Matter

It was long posited that lie detectability in high-stakes conditions will be different from that of

laboratory simulations (i.e., scenarios that include trivial lies or lies that are not of a critical nature with critical penalties, typically set within a laboratory condition or university setting and restricted by ethical concerns). It was thought that the cues that liars exhibit will be more discernible in a high-stakes situation than in a low-stakes one. Thus, the higher the stakes, the higher the chance more reliable deception cues will be elicited and thus deceit will be more likely to be detected.

Contrary to these earlier propositions, truth–lie detection in a higher-stakes scenario did not fare much better, or easier. Furthermore, there was little difference in how detectable lies were across different scenarios. These scenarios included statements moderated by the level of sender's motivation (i.e., sender is unmotivated or highly motivated) and highly emotional statements.

Response Biases in Lie Detection

The truth bias hypothesis holds that veracity judgments will always be greater than 50% for truthful statements. Observers are more likely to ascertain honest messages accurately more often than lies due to a bias toward truthful messages. The truth default theory claims that the truth default passively draws assumptions about a statement or sender. It is a cognitive default hypothesized to occur without conscious reflection and can be empirically measured via the observation of a truth bias. Essentially, the truth bias can be made with or without conscious reflection. Truth bias needs not be a cognitive default, so a judge can arrive at a truth bias without requiring a truth default; however, a truth default helps explain why a truth bias is preselected and transpires.

Conversely, the lie bias has been shown to be exhibited more often by certain groups, including police officers and prison inmates. This bias posits that observers will achieve accuracy greater than chance level in correctly categorizing statements that are deceptive compared to truthful ones.

In contrast to a default in believing or disbelieving others, the Adaptive Lie Detector account posits there are no such cognitive defaults. Instead, response biases are indications of observers attempting to make an informed guess when little information is available or when diagnostic value of cues present is low. In these cases, individuals

are theorized to adapt their decision-making according to the specific situation by using heuristics, which causes biases to surface. Contrary to the truth default theory, under the Adaptive Lie Detector account, both truth and lie biases are posited to arise from the same underlying process.

The accuracy of these theories rests on whether these response biases are inherent defaults or otherwise. Since these defaults are predominantly unconscious, it then becomes vital that the role of unconscious lie detection be revealed. To date, there is not much existing empirical evidence for unconscious but accurate lie detection.

Final Thoughts

While having the potential to aid the detection of deception, verbal and physiological tools in their current form do not meet scientific criteria in terms of relevance, probative value, and reliability. Furthermore, standing theories in lie detection research are subject to be further developed, supported, or challenged.

LIFE COURSE PERSPECTIVES ON CRIME

The life course perspective (herein, life course) is not a theory of criminal or any other behavior; rather, it is a framework within which theories can be placed to explain behavior. Life course recognizes that human beings move through the life span (birth to death) in a series of age-graded events and roles that are conditioned by history and social structure. Research in several disciplines (e.g., psychology, criminology, biology) utilizes life course to explain patterns of human behavior and life events. The life course perspective on crime is used to explain individuals' pattern of criminal behavior over the life course, including the onset (how an individual begins involvement in crime), frequency, and duration. The main objective of life course on crime is to study changes *within* individuals over time with respect to risk factors and life events and to relate them to changes in offending. Traditional criminological theories focused on why some individuals commit crime and others do not, which led to *between*-individual comparisons and several known correlates of crime (e.g., sex, age, race). Although understanding correlates of crime is important, life course recognizes that there is variability *within* individuals, not just *between* them, and this may help explain patterns of illegal behavior.

Life course examines how critical life events affect stability and change in individuals' behavior over time. The life course is conceptualized as *trajectories* and *transitions* through the age-differentiated life span. A trajectory is a line of development through life (or a pathway) in life domains such as marriage, work, parenthood, or criminal behavior; trajectories refer to longer term patterns of behavior. Transitions are specific life events embedded within trajectories and evolve over shorter time spans, such as getting married or the onset of crime. The life course is driven by individuals' trajectory, but transitions may serve as turning

points or changes in individuals' trajectory. Thus, the life course perspective has two major constructs that it seeks to explain with regard to crime: *continuity* and *change*. Continuity refers to the stability between childhood or adolescent experiences and adult outcomes, whereas change refers to different or modified life course trajectories. After reviewing the origins and development of the life course perspective, this entry discusses some of the prominent life course theories of crime.

Origins and Development of the Life Course Perspective

Sociologist Glen Elder Jr. is widely recognized as the father of interdisciplinary life course research, as his research drew attention to people's *lived experiences* and the importance of historical and social context in the study of human lives. Elder's research stimulated many scholars to take interest in the collection of longitudinal data that describe people and their social contexts over time. These insights and the life course paradigm he formulated transformed the way scholars conceptualized problems, measured concepts, and analyzed and interpreted data. Although Elder never applied the life course perspective to the study of crime, its application to criminology is straightforward.

Early Formative Longitudinal Studies in Criminology

William Isaac Thomas and Florian Znaniecki set the foundations for many perspectives on crime, including the life course perspective. In 1918, they published their analysis of the lives of Polish peasants as they confronted the inevitable conflict with U.S. culture. A few decades later, in 1950, Eleanor Glueck and Sheldon Glueck collected data utilizing a matched sample prospective design of boys living in underprivileged areas in Boston. They matched 500 delinquent boys to 500 nondelinquents by age, race or ethnicity, IQ, and neighborhood socioeconomic status and compared their patterns of criminal behavior over a period of 25 years using both official records and personal interviews. They looked at key social, psychological, and biological factors, changes in salient life events (e.g., marriage, employment,

military involvement), patterns of offending, and official criminal justice interventions (arrest, incarceration). The subjects were interviewed as juveniles (average age 14 years), at age 25, and age 32. The Gluecks suggested that delinquency was rooted in early childhood experiences, with discipline and family life being significant. Their findings revealed that misbehavior and delinquency begins long before kids reach adolescence and signs are often visible by the time children are between 3 and 6 years of age, and almost always before they are 11 years of age.

Further research studied birth cohort and found that only 6% of juvenile boys living in Philadelphia accounted for over half of the crime in the entire sample. They found that these youth were habitual, chronic, high-rate offenders, or what came to be known as *career criminals*. A similar study followed the lives of 411 London boys born around 1953 for a period of nearly 25 years. They also found a strong relationship between the criminality of an adult and his or her behavior as a child. These early studies supported the concept of continuity in antisocial behavior from childhood through adolescence and adulthood. These studies also highlighted the importance of age, deviant peers, family influence, and socioeconomic background for understanding the onset, frequency, and desistence of criminal behavior.

The Age–Crime Curve and Criminal Career Debate

Some of the most heated controversies within life course are concerned with the age–crime curve (that criminal behavior typically peaks at the age of 17–18 years, before beginning to decline in the early 20s) and criminal careers. The relationship between age and crime is well known but scholars disagree on its interpretation. Some argued the age–crime curve was similar for all offenders, whereas others argued that meaningful differences could be found within the curve, suggesting that different types of offenders exist (with distinctive developmental courses).

It has been argued that the amount of crime committed over an individual's life could be explained by four distinct parameters: the age of onset, frequency of offending, duration of career, and age of termination (desistance). Proponents of

this view argued there could be one set of factors that influenced whether someone participates in crime and another set of factors that affects the frequency and duration of the person's criminal acts. However, others argued that it was not necessary to study these four allegedly distinct parameters to understand the causes of crime because it was stable individual differences in self-control that accounted for how much crime an individual committed over his or her life course. They also argued there was a direct effect of age on crime that was invariant across persons, time periods, and crime types, making the need for longitudinal studies unnecessary.

Prominent Life Course Theories

A key assumption of life course is the idea that criminals progress through different life stages, and there are over a dozen criminological theories that fall under this perspective. As noted, life course is not a specific theory; rather, it is a framework within which scholars can place their theories. Two of the most renowned theories are Terrie Moffitt's dual taxonomy and Robert J. Sampson and John Laub's age-graded social control theory.

Moffitt's Dual Taxonomy of Antisocial Behavior

In 1993, Moffitt argued the aggregate age-crime curve is composed of two distinct offender profiles. The first type, life course-persistent, includes a small group of individuals (~5–8%) who exhibit early, chronic, persistent, and serious forms of antisocial and delinquent behavior that emerges early in childhood and persists throughout the life course (adolescence, adulthood). Life course-persistent offenders tend to experience socioeconomic disadvantages and display neuropsychological deficits early in life (e.g., poor listening and problem-solving skills, learning problems). These deficits create problems when interacting with parents early in life, which leads to social conflicts later in life with peers, teachers, and other authority figures. Moffitt refers to this pattern of problematic and destructive interactions as *cumulative continuity*, whereby the consequences of poor interactions perpetuate a child's, and later an adult's, tendency for antisocial behavior. Life course-persistent offenders are

unlikely to desist from antisocial and criminal behavior. Thus, Moffitt assumes that habitual and serious criminals can be identified early in life and will remain on their antisocial trajectories for the rest of their lives.

The second group of offenders is referred to as adolescent-limited (AL) because their offending behavior is typically restricted to the adolescent phase of the life course. Moffitt argues AL offenders are frustrated because they desire to attain adult privileges, resources, and responsibilities but cannot legitimately do so. Restrictions on their behavior cause AL offenders to be influenced by the delinquent activity of their peers through a process of social mimicry and observational learning (e.g., underage drinking, risky behavior). Although AL offenders engage in delinquency for a time, most age out of it as they mature and adult roles become available.

Sampson and Laub's Age-Graded Theory of Informal Social Control

Also in 1993, Sampson and Laub reanalyzed data from the Gluecks' study and used life course combined with control theory to frame their analyses of offending patterns across various life stages. They developed a theoretical framework to explain both stability and change in antisocial behavior over the life course. Their basic thesis is that while continuity in deviant behavior exists, social bonds in adulthood (to work, family, and community) explain changes in criminality over the life span. Their model also acknowledges the importance of early childhood behavior and experiences for understanding behavioral stability. They observed how various life course transitions (e.g., getting married, getting a new/better job, having a child) take individuals off an antisocial trajectory and onto a prosocial one. These transitions are turning points reflected in increased informal social control and a stronger bond to society. A key thesis of their theory is that crime is more likely to occur when an individual's bond to society is attenuated.

Sampson and Laub contend factors at earlier life stages can influence individuals' criminal propensity at later life phases (behavioral stability); however, experiences in adolescences and adulthood can redirect criminal trajectories in a

positive or negative way. They also consider the idea of *cumulative continuity*, like Moffitt, whereby antisocial behavior early in life undermines social bonds, which then reduces youths' prospects of participating in later prosocial experiences. This continues the cycle of antisocial behavior, which may lead to a life of offending.

Their theory is age-graded, which emphasizes informal social controls that occur at different life stages (i.e., childhood, adolescence, adulthood). For example, parenting styles and emotional attachment to parents are paramount in childhood; attachment to peers and school is central in adolescence; and marital stability, employment, and military service are important in adulthood. Sampson and Laub's findings have supported the notion that antisocial behavior in childhood is linked to delinquency in adolescence and to crime, alcohol abuse, and general deviance in adulthood. Thus, they asserted that criminality is not a constant but is affected by the larger social forces that change over the life course.

Laub and Sampson continued to follow up the Glueck sample and refined their theory to include routine activities and *human agency* (the purposeful execution of choice and individual will). For example, they found that men who desisted from crime were active participants in the process. According to their revised theory, social control, social structure, routine activities, and human agency, both directly and indirectly, affect trajectories of crime across the entire life course.

New methodological and statistical techniques developed during the early 2000s, such as group-based modeling of developmental trajectories, have helped scholars get more out of their longitudinal studies, giving the life course more robust empirical standing.

LOW INTELLECTUAL FUNCTIONING IN INCARCERATED OFFENDERS, TREATMENT OF

In prison and jail, inmates with low intellectual functioning (i.e., IQ below 70) tend to be at greater risk of both violent behaviors and victimization due to their difficulty in responding to social cues and adjusting to a stressful environment. Those with intellectual disability comprise 2–3% of the general population but represent

4–10% of the prison population, with an even greater number in jails. One study examined the number of people with disabilities in state and federal prisons and discovered that less than 1% of the prison population had some type of physical disability with 4.2% experiencing a form of intellectual disability. Those with lower intellectual functioning tend to have special needs and may experience difficulties in verbal comprehension, perceptual reasoning, memory, attention span, and processing speed. In addition, they may have medical and mental health issues associated with their cognitive impairments. Without their special needs addressed, these individuals can be easily taken advantage of and/or act out in frustration. This entry provides an overview of how inmates with lower intellectual functioning face disadvantages in prison; examines how to assess these inmates; discusses whether to house them separately or with the mainstream population; and then explores how to habilitate, effectively treat, and prepare these individuals for reentry.

Lower Intelligence a Disadvantage in Prison

Those with lower intellectual functioning typically have some corresponding deficits in adaptive functioning. These deficits can be in the social arena, where an inmate can be more gullible, easily manipulated, and personally irresponsible. Deficits can be in practical areas, such as difficulties in their eating, dressing, feeding, or toileting, and it can be instrumental deficits such as having difficulty using the telephone, managing money, maintaining a safe environment, and performing routine job skills.

In addition, those with lower intellectual functioning are more likely to have an intellectual disability characterized by limitations in both intellectual functioning and adaptive behavior that originates before the age of 21. Adaptive behavior is the reversible aspect of intellectual disability and relates to the conceptual, social, and practical skills that all people learn in order to function in their daily lives. Offenders with lower intellectual functioning are also more likely to have an associated developmental disability (i.e., a lifelong disability contributing to both mental and physical impairment other than mental illness,

usually manifesting before the age of 22 years and likely to continue indefinitely). These include autism spectrum disorders, intellectual developmental disorder, and Down syndrome.

Accurate Assessment a Prerequisite to Treatment

In preparation for treating an inmate with lower intellectual functioning, it is essential to have accurate screenings of deficit areas. Most jails and prisons offer screening at reception by asking specific questions to inmates with regard to disability: Can they tell time? Do they know how to manage their money? Can they take their own medications independently? Have they ever driven a car? Have they ever received services for developmental disabilities? Were they in special education classes in school? Are they receiving Supplemental Security Income or Social Security Disability Insurance through the Social Security Administration? In their developmental years did they have any serious physical trauma and/or congenital condition that impacted their functioning? If screening suggests an intellectual or developmental disability, inmates usually are targeted for a more thorough assessment. In prison, it is performed by a mental health professional and usually includes a standardized IQ test and a more thorough assessment of adaptive functioning. As part of a full assessment, mental health problems are evaluated, and often this population will exhibit symptoms of depression and/or anxiety. It is important to separate those with lower intellectual functioning from those who have mental health disorders independent of low intellectual functioning. Large jails and prisons may have special mental health units to separate inmates with mental illness from the general population. Often special dockets in local courts identify plans of assistance and supervision for those with lower intellectual functioning.

The needs of this population are very specific and require an approach by jail and prison staff that is individualized, repetitious, and finds ways to focus on the strengths of the inmate. The inmate's strengths often are the means used to work toward habilitation. For example, if an inmate has strengths in his or her perceptual reasoning, it would be advantageous for staff to show

him or her how to do things rather than just give verbal instructions. Thorough screening and assessment is the beginning of the treatment process for those with low intellectual functioning.

Mainstream or Separate?

A major issue of those assisting lower intellectual functioning inmates in prison and jail is whether to mainstream the individual among the general population or separate them, placing them into special housing units where special needs programming and/or enhanced supervision can be provided. Some prisons, such as in Ohio, have their own special needs programs housed with enhanced treatment staff for those with low intellectual functioning who are considered to have intellectual disability. One consideration for placement is how vulnerable the individual is to be victimized by others in general housing. Those with lower intellectual functioning have historically been more traumatized and victimized in jail and prison because they are more easily influenced, may be more eager to please others, often believe the perpetrator is their friend, and may be less able or likely to report being victimized. In addition, those with intellectual disability tend to have longer prison sentences because it is harder for them to adjust to the prison environment, and they take longer to complete programs.

Those with intellectual disability who stay in general population may need treatment including specialized services, such as a work assignment or classes that present materials in a more concrete and systematic way. Those with lower intellectual functioning in prison often have greater difficulty understanding instructions. They seem to have a lower frustration tolerance and may have outbursts that get them noticed or get them extra punishments for violations. They also seem to have a greater difficulty with impulsivity, often not thinking before they act, which may get them noticed quickly in a jail or prison setting.

Stigmatization and Habilitation

Those with lower intellectual functioning often get judged in a negative way by those with average intelligence. Sometimes their physical appearance may seem a bit odd or unusual. They may have

motor problems and other physical limitations. In addition, it may be obvious to other inmates that this population has difficulty comprehending and can be easily manipulated or victimized.

Even staff may have difficulty understanding this population's limitations and think that they are intentionally disobeying, although they may actually not understand what is being asked and/or may misread situations. This points to the need for thorough staff training, so staff can be the eyes and the ears for this population, learn effective approaches, and possibly even protect them from victimization. Staff may need to speak in shorter, simple sentences, repeat instructions, and show more empathy for the limitations of these offenders. In addition, staff may need to learn what types of plans work with this population and how to better assess their needs. Staff may need to spend more time listening and repeating instructions. They also may need to understand how to help the offender with intellectual disability with daily living tasks and other habilitation needs. For example, staff may need to demonstrate tying of shoes, helping the offender shave and/or bathe, and/or helping the offender count and budget money. In this sense, staff members are seen as teachers and role models, and their patience and ability to break tasks down into steps is crucial in delivering services.

Finally, staff may need to help the offender with intellectual disability in identifying feelings and learning ways to cope with feelings. For example, anger can be overwhelming to somebody with lower cognitive functioning, and he or she may need to be taught simple coping strategies (e.g., walking away from a fight, doing deep breathing exercises, and/or asking for help when he or she becomes overwhelmed). The ability to identify emotions can sometimes be a major obstacle for this population. It is best to help them identify very basic emotions such as anger, sadness, happiness, and anxiety. Often these emotions are learned by pairing them with concrete cues such as faces drawn on paper or simple emotive events such as a funeral or a wedding.

Treatment Programs

In prison, there are specialized programs designed to meet the needs of the offender with intellectual

disability. In jail, typically due to the shorter stays, a higher level of supervision is provided. There seems to be a high concentration of sex offenders with intellectual disability represented in prison. Most sex offenders in prison either have committed rape or are pedophiles. These inmates typically need to be in a sex offender group and/or have individual counseling where they are held responsible for learning the thinking errors that contributed to their offenses and the cycle that led them to sexually offend. They need to learn basic relational skills so they can learn how to be intimate in relationships rather than predatory.

Part of the treatment for inmates with intellectual disability has to do with either vocational opportunities and/or schooling, depending on the age of the inmate. These classes are specialized because the curriculum is tailored for those with lower intellectual functioning. Those with a developmental disability can do classroom work up to the age of 22 years. Vocational experiences need to be very individualized and usually provide work coaches and more repetitious simple tasks. It offers these inmates the opportunity to develop some work skills that may be helpful when they leave the institution. Those with lower intellectual functioning usually upon returning to the community will go into sheltered jobs where the work is more structured and provides more intensive supervision.

Treatment for those with lower intellectual functioning also consists of special programs to address adaptive deficits when the inmate cannot perform specific skills independently (e.g., grooming, money management, basic cooking skills, or washing clothes). The programs usually incorporate prompts given by line staff who help the individual break the task into simple steps that are progressively taught until the skill is mastered. Due to the inmates' lower intelligence and poor comprehension, some skills may take months or even years to learn.

Another type of treatment is teaching social skills or anger management to those who have trouble problem-solving and interacting appropriately with others. Often these skills are taught in groups led by an instructor who encourages role-playing of basic social skills. The group provides the individual with feedback on how best to respond in frustrating situations. Those with low

intellectual functioning often have trouble reading social situations and are limited in their knowledge of how to reduce stress and work through common problems (e.g., how to handle a complaint constructively, how to calm down, how to listen to others effectively, and how to wait to receive something desired). Specific scenarios are usually tailored for the specific problems of each group member based on what kinds of situations have gotten each inmate into trouble in the past.

Reentry Plans

It is key early in jail and prison stays for the offender with low intellectual functioning to have a case manager who looks for resources in the community that will support reentry. Some states have specific systems set up to work with those with intellectual disability and/or developmental disability. Sometimes these systems provide monies for housing, programming, and health care. However, due to the specialized needs and services, it may take a lot of planning, time, and effort to find an inmate eligible and to place him or her on the waiting lists for the needed services. The jail and prison caseworker and treatment providers need to reach out to providers in the community to allow the system to have time to prepare for the inmate's reentry. Often questions of risk and need can be asked at an early stage of incarceration so that supports can be developed in the community, thus giving the offender a greater chance for success upon reentry. Although reentry has been a concept embraced by professionals for many years, it usually is a time-consuming, specialized process for those with low intellectual functioning. Historically, there has not always been good communication between jails or prisons and the service delivery system where the offenders will be returning; thus establishing relationships between jail or prison staff and community providers early on is vital to meeting special needs. An inmate with lower intellectual functioning should be released with an integrated plan of treatment options to meet his or her needs.

M

MAJOR DEPRESSIVE DISORDER IN INCARCERATED OFFENDERS, TREATMENT OF

Major depressive disorder (MDD) is termed a *serious mental illness* and has a 12-month prevalence of approximately 7% in the United States. The prevalence of MDD in prison populations is slightly higher, with the condition affecting approximately 10% of incarcerated males and 12% of incarcerated females, although some studies report rates as high as 25% in prison populations. The World Health Organization has predicted that MDD will be the most problematic disease in the world in the 21st century. Despite this, there is little research regarding treatment of MDD in prison populations. This entry begins with a brief discussion of the hallmark symptoms of MDD and then moves to discussions of diagnosis/assessment, etiology/course, treatment, and adjustment to prison life, particularly as it relates to depression.

Symptoms of MDD

The hallmark symptom of MDD is the experience of at least one major depressive episode. By the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* definition, major depressive episodes last for at least 2 weeks and reflect a change in functioning for the individual. The symptoms of major

depressive episodes are operationalized as nine distinct criteria of which an individual must meet five in order to be diagnosed. The first two symptoms of a major depressive episode consist of depressed mood and a significant decrease in interest or pleasure. One of the five symptoms must include either of these first two symptoms. Significant fluctuations in weight (either loss or gain) and sleep (either too much or too little) are additional symptoms of a major depressive episode. The presence of either purposeless movement (i.e., psychomotor agitation) or reduced movement is a sign of a major depressive episode. Fatigue, feelings of worthlessness or guilt, and concentration problems are additional symptoms of a major depressive episode. The final symptom of a major depressive episode is thoughts of suicide or a suicide attempt. As noted, if at least five of these nine symptoms are met and are present for at least 2 weeks, the criteria for a major depressive episode is met and the individual may be diagnosed with MDD. There are additional psychiatric diagnoses that may include major depressive episodes as well such as bipolar I disorder and bipolar II disorder.

Diagnosis and Assessment of MDD

MDD is overrepresented in females. Assessment of MDD is most often made through a detailed clinical interview that probes an individual's symptom history and current and past functioning. Widely used psychological tests such as the Minnesota Multiphasic Personality Inventory and

the Personality Assessment Inventory both purport to assist in diagnosing MDD. Brief screening measures for MDD include the Beck Depression Inventory and Beck Hopelessness Scale.

Etiology and Course of MDD

As with most complex conditions, MDD is considered multifactorial in nature and is thought to stem from a combination of biological and environmental factors. Not surprisingly, there is a high degree of comorbid mental health conditions in individuals with MDD. In terms of genetics, twin studies suggest a heritability of approximately 37% in MDD. First-degree family members of someone with MDD are 2–4 times more likely to develop MDD when compared to the general population. The monoamine-deficiency hypothesis suggests that MDD is caused by a reduction in the brain neurotransmitters serotonin and/or norepinephrine. The hypothalamic–pituitary–cortisol hypothesis suggests that an abnormality within the brain’s processing of stress and release of cortisol underlies MDD. Structural neuroimaging studies have found abnormalities in various brain regions including the hippocampus and anterior cingulate gyrus. Functional neuroimaging studies have proffered a variety of hypotheses including underactive frontal lobe functioning and increased thalamic pulvinar activity.

For 80% of individuals with MDD, recovery begins within 1 year of the onset of a major depressive episode. However, the course is quite variable. One particular study followed individuals with MDD for 15 years. Following the initial major depressive episode, 85% of those individuals experienced an additional episode. Few predictors distinguished those who made a full recovery but female gender, having more prior episodes, and never marrying predicted future depressive episodes.

General Treatment of MDD

Treatment of MDD falls into two broad categories: medication and psychotherapy. Often, it is the combination of both medication and psychotherapy that provides the most benefit in MDD.

There are many classes of medications used to treat MDD. The most common class is the

selective serotonin reuptake inhibitors. This class of medication includes fluoxetine (Prozac), paroxetine (Paxil), sertraline (Zoloft), and citalopram (Celexa). There are also medications classified as serotonin–norepinephrine reuptake inhibitors and norepinephrine–dopamine reuptake inhibitors. Examples of serotonin–norepinephrine reuptake inhibitors include duloxetine (Cymbalta) and venlafaxine (Effexor). Serotonin–norepinephrine reuptake inhibitors are noted to be particularly helpful with the pain-related symptoms that are often associated with depression. Bupropion (Wellbutrin) is an example of the norepinephrine–dopamine reuptake inhibitors, and it is one of the few antidepressants with few sexual side effects. Older classes of antidepressant medications include the tricyclics and the monoamine oxidase inhibitors. However, at this point, they are not considered first-line treatments for MDD because of their side effect profiles. Examples of tricyclics include nortriptyline (Pamelor), imipramine (Tofranil), and desipramine (Norpramin). Examples of monoamine oxidase inhibitors include phenelzine (Nardil) and tranylcypromine (Parnate). There are also several *atypical* antidepressants including mirtazapine (Remeron) and trazodone (Desyrel). These medications are sedating and usually taken at night to assist with insomnia related to depression.

There are multiple evidence-based psychotherapies used in the treatment of MDD. These include behavior therapy/behavioral activation, cognitive therapy (CT), cognitive behavioral analysis system of psychotherapy, interpersonal therapy, problem-solving therapy, self-management/self-control therapy, acceptance and commitment therapy, behavioral couples therapy, emotion-focused therapy, rational emotive behavioral therapy, reminiscence/life review therapy, self-system therapy, and short-term psychodynamic therapy. The most widely used psychotherapy for depression is Aaron T. Beck’s CT, and this is discussed in some detail in the following paragraphs.

CT has been researched extensively, and its efficacy is well-documented. There is also a significant body of research showing that CT has significantly lower relapse rates than pharmacotherapy at 1- and 2-year follow-ups. CT is based on the idea that a person’s affect and behavior are primarily the result of the way in which the person

structures or thinks about the world. The theory holds several assumptions. First, the way in which a person views his or her situation can be gleaned from the person's cognitions. Second, these cognitions are based on attitudes (schemas), which are created by previous experience. Finally, changing one's cognitive structures changes one's affective state and behaviors. In other words, you can change your emotions and actions by changing your thoughts.

Within CT, there are three main concepts used to explain depression: the cognitive triad, schemas, and cognitive distortions. The cognitive triad can be thought of as a style of thinking in which a person views the self, future, and world in a negative way. Second, a schema can be thought of as a stable cognitive pattern and becomes the filter through which all information is processed. In the case of a depressed person, his or her negative schemas cause him or her to misinterpret information, which helps to perpetuate his or her depression. Typically, schemas can be classified as belonging to either one or both of two broad categories: those dealing with helplessness and those dealing with unlovability. Another important facet to schemas is that they can be dormant for periods of time but can be activated or reactivated by circumstances that are tantamount to the experiences initially responsible for instilling the negative belief. Third, depressed individuals often show distorted thinking, which is the result of the activity of negative schemas. Therefore, cognitive distortions, or faulty information processing, are the result of and maintain one's belief in negative concepts and schemas. Thus, cognitive distortions perpetuate depression despite contrary evidence. Some types of cognitive distortions are dichotomous thinking (i.e., the tendency to view situations in only two categories instead of on a continuum), personalization (i.e., the erroneous assumption that others are behaving negatively because of you), and labeling (i.e., the placing of global, fixed labels on oneself or others).

Treatment of MDD in Prison

There is surprisingly little research on the treatment of depression in incarcerated populations, as treatment studies have tended to focus more on reducing rates of recidivism and substance abuse.

What research exists regarding depression has mainly examined nonevidence-based treatments such as bibliotherapy, art therapy, and music therapy. However, these treatments have been found to be helpful in reducing depressive symptoms in inmates. Medication management of depression in prison is common with some reports indicating that 10% of prisoners are prescribed some type of psychiatric medication.

Adjustment to Prison Life and Avoiding MDD

To the extent that prisoners can adjust to prison life, they will experience a reduction in rates of depression, anxiety, stress, suicidal behavior, and violent infractions. Factors related to prison adjustment traditionally fall along two broad dimensions: variables that prisoners import into prison and deprivation features of prison also known as the *pains of imprisonment*. Most researchers now believe that both importation and deprivation factors influence prisoners' adjustment to incarceration.

Regarding factors *imported* into prison, some research has found that female gender confers a greater psychiatric vulnerability among first-time prisoners. Research has shown that female prisoners have greater social support needs than males, and increasing social support can improve adjustment to prison. In addition, other importation factors known to affect adjustment include educational level, quality of life prior to prison, amount of substance use, the presence of antisocial traits, having a prior criminal record, race, degree of religious practice/affiliation, and age.

Regarding deprivation features of prison, a more restrictive setting increases psychological maladjustment, including depression. In addition, other deprivation factors known to affect adjustment include staff behavior, level of gang activity, program availability, and overcrowding. The length of prison sentence is nonlinear in its relationship to prison adjustment and approximates more of a U-shaped relationship. One study also found that some prisoners who had a *good* adjustment to prison were those who learned new skills while incarcerated that they thought would carry over once released (e.g., a new job skill). Deprivation variables such as level of restriction,

overcrowding, and violence are also strongly linked with prison suicide.

Researchers have suggested that emotion-focused coping strategies can assist in prisoners' adjustment to incarceration and, thus, reduce depressive reactions. Examples of these strategies include distraction, meditation, regular exercise, practicing forgiveness, and sharing rather than suppressing negative emotions.

MALINGERING

Malingering is defined by the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* as the intentional fabrication or gross exaggeration of psychological or physical symptoms, with the key criteria of being motivated by some external gains. In the context of an offender population, these motivations may include (a) delaying or reducing the length of incarceration, (b) being prescribed unnecessary medication, or (c) receiving unwarranted benefits (e.g., compensation for a feigned disability). As a response style, malingering is categorized as a condition that may be a focus of clinical attention rather than as a formal diagnosis with explicit inclusion and exclusion criteria. Within the psychological and medical fields, malingering and other forms of deception represent a highly relevant clinical issue

for accurate assessment and effective treatment of offenders.

This entry provides a broad overview and understanding of malingering in the context of criminal psychology. In particular, some common myths and misconceptions of malingering are addressed. The prevalence of malingering in forensic settings and broad subtypes of malingered presentations are then discussed. This is followed by an overview of response styles that have been developed to conceptualize malingering. Given the focus on criminal psychology, individuals being evaluated will be referred to as *offenders* rather than *clients* or *patients*. As a key emphasis of this entry, the development of detection strategies for malingering and a focus on commonly used measures of malingering are highlighted.

Malingering Within the Forensic Setting

In the context of criminal psychology, a small subset of offenders may perceive a strong advantage for malingering to avoid potentially extreme consequences, such as lengthy incarcerations. For example, successful malingering during an insanity trial might result in extended hospitalization that avoids decades of prison time. This externally motivated feigning is distinguished from factitious disorders. For the latter diagnoses, individuals intentionally produce exaggerated symptoms in response to some internal motivation, such as treatment seeking. It should also not be confused with poor or suboptimal effort, which may occur as a result of genuine psychopathology in examinees who have no intention to fake impairment. From this perspective, malingering is highly relevant to criminal psychology because it is a potential mechanism through which offenders can attempt to achieve their external goals. At the same time, however, unsuccessful malingering can have extremely negative consequences that may include increased sentencing and the limiting of treatment options, even for genuine disorders.

Professionals in criminal contexts may experience an understandable inclination toward adopting a *negative bias*, in assuming the worst about their clientele. On the contrary, many offenders have genuine mental disorders. Thus, it would be unduly biased to assume that most criminals are just *gaming the system*. Even when confronted

with the death penalty, as an extreme example, most convicted offenders do not malingering despite facing their imminent execution. Therefore, professionals have been urged to conscientiously evaluate malingering in each individual case and not simply assume a negative bias toward criminals.

Fundamental Misconceptions About Malingering

Common and potentially damaging misconceptions are often observed concerning malingerers and the nature of malingering itself. It is essential to identify and refute such serious misconceptions, which may lead to false conclusions with far-reaching consequences. Five key misconceptions are outlined:

- *An offender who grossly exaggerates in one domain must be malingering in all domains.* Therefore, all symptoms should be dismissed as bogus. This all-or-nothing misconception of malingering overlooks the clinical observation that many—if not the majority of—malingerers also have genuine disorders. Also, malingering cannot be considered a permanent response style but rather represents a situational response to a specific context.
- *Inconsistent responding is tantamount to malingering because feigners often have trouble being consistent.* Possibly stemming from the negative bias, this misconception myopically views malingering as the only cause of inconsistency. Marked inconsistencies can also arise from clinical issues and cognitive impairment. For self-administered measures, for example, limited ability to read or impaired concentration frequently contributes to pervasive inconsistencies.
- *Malingerers are easy to identify because their presentations are obviously exaggerated.* Some medical and mental health professionals may have overly positive appraisals of their abilities to accurately evaluate malingering. Such misappraisals can stem from encountering egregious cases of unskilled and preposterous efforts at malingering. However, many malingerers are more skilled and less obvious in their feigned presentations; they can only be

detected by standardized measures that employ—as described below—well-validated detection strategies.

- *Malingering and other forms of deception occur in most forensic cases.* This misconception again reflects a negative bias more than a conceptual or empirical basis. Although certainly true that malingering occurs in a small subset of offenders, research suggests that malingering is neither rare nor pervasive. Furthermore, this concept ignores the full spectrum of possible deception from white lies to sophisticated frauds, within which malingering is distinguishable as a very specific and clinically relevant response style.
- *Malingering and genuine mental disorders are mutually exclusive.* A particularly detrimental assumption is that malingering precludes the presence of a genuine mental disorder for an individual. However, an offender may wish to feign some particular symptoms (e.g., psychotic symptoms in order to be found incompetent to stand trial) but genuinely has a severe mental illness (e.g., depression or anxiety). If all of an examinee's symptoms are summarily dismissed once exaggeration is noted for some symptom domain, the offender may fail to receive much-needed mental health care.

Prevalence Within Forensic Settings

Importantly, the majority of offenders being assessed do not attempt to mangle during evaluation; however, it occurs with sufficient regularity that its assessment is essential. In recognition of these concerns, the American Psychiatric Association began to encourage the use of screening criteria for malingering with the third edition of the *Diagnostic and Statistical Manual of Mental Disorders* in 1980. Although its prevalence is by nature difficult to assess, extensive surveys have suggested base rate estimates of malingering ranging from approximately 10% to 20% in forensic settings. Malingering and related response styles have been consistently recognized as an important clinical concern for criminal psychology, particularly because forensic assessments differ substantially from typical assessments.

In the context of mandated evaluations, both system (e.g., the pressure of required participation)

and personal factors (e.g., unfavorable consequences from accurate self-disclosures) lead professionals to consider whether offenders are malingering. Contrastingly, most individuals in typical inpatient or outpatient settings seek treatment of their own volition and are motivated to receive accurate results from their psychological testing. In most instances, they are also protected from negative consequences by the guarantee of confidentiality. In forensic contexts, however, clinician–client relationships are fundamentally altered. Within correctional settings, for instance, professionals work for the institution or legal system rather than the offender being evaluated. Typically, these clinicians are professionally obligated to report negative findings that may include malingering and uncooperativeness as well as any institutional misconduct.

Offenders may have substantial motivation to malingering, especially when faced with high-stakes legal outcomes. For competency to stand trial, a finding of incompetence may lead to a delay of the criminal trial along with the modest benefits of a forensic hospital rather than a county jail. For insanity at the time of a crime, an acquittal may lead to better living conditions and possibly fewer years of confinement, although the length of sentences depends largely on the jurisdiction. However, many offenders may view malingering as an unacceptable risk because of the serious negative consequences associated with unsuccessful feigning. For instance, offenders pleading insanity are essentially admitting to the criminal acts while also raising questions about their mental state. If found to be sane and malingering, a conviction is almost a certainty, while the malingering could contribute to an even longer sentence.

Subtypes of Malingering

Although malingering shares some key similarities across contexts (e.g., fabrication of symptoms for an external goal), research has clearly demonstrated its complexity, which includes several domains and varied motivations. Three subtypes of malingering are identified within a criminal context:

- *Feigned mental disorders: Offenders in this domain simulate severe psychopathology and*

marked psychological impairment. For example, inmates may fabricate severe psychiatric symptoms in order to receive unwarranted medications so that they can do easy time.

- *Feigned cognitive impairment: Offenders simulating cognitive impairment (e.g., learning or intellectual disability) intentionally fail cognitive tasks rather than fabricating symptoms per se. Relevant examples include a fraudulent person malingering cognitive problems resulting from an automobile accident in order to maximize personal injury compensation or a defendant feigning an intellectual disability so as to be found incompetent to stand trial.*
- *Feigned medical complaints.* This subtype includes offenders who exaggerate or fabricate symptoms of physical illness, pain, or disability. As an example, a claimant may malingering chronic pain in order to be awarded workers' compensation. In addition, inmates may simulate a chronic medical condition to avoid institutionally required work responsibilities. Again, as an important distinction, feigned medical impairments are motivated by external gain, whereas factitious disorders use simulated physical symptoms for internal needs.

Overview of Response Styles

Response styles refer broadly to the intentional misrepresentation of psychological information in order to manipulate how examinees are perceived. These response styles may range from total denial to complete fabrication of symptoms, in service of identified goals. More specifically, the intent may be to create either a more positive (e.g., faking good by denying substance abuse) or negative (e.g., faking bad by exaggerating psychotic symptoms) impression. Other, less intentional response styles (e.g., irrelevant or random responding) are also possible but typically reflect an examinee's lack of engagement in the assessment process rather than a deliberate attempt to portray a specific presentation. Having recognized that various levels of deception may occur across different settings, patients, and disorders, it is important to emphasize that response styles discussed here apply only to intentional and goal-motivated deception.

The importance of evaluating response styles on psychological measures has been long recognized

in the field of psychological assessment because extensive research has demonstrated that most response styles can markedly distort or even nullify the validity of test results. To address their vulnerability to response distortion, some psychological tests, especially multiscale inventories, began in the 1940s to develop and implement scales to detect response styles. These scales, often referred to as *validity indices*, utilize specific detection strategies as a systematic approach to detect response distortion. Several common strategies—specific to malingering—are discussed in greater detail in the following section.

Detection Strategies for Malingering

Accurate evaluation for potential malingering is often challenging because the assessment of mental disorders relies predominantly on self-reported symptoms and subjective distress. Persons with severe mental disorders often sincerely lack insight into their psychopathology. Therefore, the challenge of validity indicators is to differentiate genuine efforts (e.g., poor insight) from intentional distortion (e.g., malingering) to improve the methodological precision of psychological measures. Focusing on malingering, research has clearly established that detection strategies tend to be most successful when they focus on separating feigned versus genuine presentations for a particular domain. Commonly used detection strategies fall into two broad categories that can be applied to feigned mental disorders: unlikely presentations and amplified presentations.

- **Unlikely presentations:** *This category encompasses detection strategies that represent highly unusual clinical presentations. Examples include (a) symptoms rarely observed among genuine patients and (b) fantastic or absurd symptoms. Going beyond individual symptoms, other detection strategies rely on unlikely pairs of symptoms or improbable patterns of symptoms. For example, it would be very unlikely for an individual claiming to be paranoid to be observed trusting most strangers.*
- **Amplified presentations:** This category of detection strategies relies on identifying malingers based on the intensity of their clinical presentations. Examples of intensity

include the (a) breadth of symptoms (e.g., endorsing too many in an apparently indiscriminant manner), (b) severity of symptoms (e.g., reporting extreme and unbearable distress), and (c) frequency of symptoms (e.g., describing continuously present psychotic symptoms). For this category, malingers severely exaggerate the intensity of symptoms beyond what is commonly reported by genuine patients. The crucial difference lies in the excessive magnitude of the purported impairment.

Clinical Assessment

Within the context of criminal psychology, offenders may have much to gain by malingering or much to lose by being honest, so careful and comprehensive clinical assessment is essential. Comprehensiveness is typically the best method for the detection of falsified responding, especially with skilled or coached malingerers, who can provide a sophisticated approach to feigning. To highlight an important distinction, psychological assessments can truly only evaluate for feigning (i.e., the exaggeration or fabrication of symptoms, with no assumptions about the nature of the individual's motivations), not malingering, because psychological tests cannot definitively establish an offender's particular, and sometimes complex, motivation. Several effective screening measures have been developed, including the Structured Inventory of Malingered Symptomatology and the Miller Forensic Assessment of Symptoms Test. However, screens are intended to be highly efficient at identifying possible cases (i.e., *quick and dirty* approach). Because of their brevity, they sacrifice accuracy for efficiency. Therefore, screens cannot be used to definitively determine that an examinee is feigning.

This section highlights three comprehensive measures of feigning, including multiscale inventories and interviews. The two most commonly used multiscale inventories for patterns of psychopathology that include multiple measures of feigning are the Minnesota Multiphasic Personality Inventory-2 and the Personality Assessment Inventory. Extreme elevations on these validity indicators can be interpreted as evidence of feigning. Importantly, moderate elevations can

only be used as screens; they indicate the need for further assessment with specialized measures for malingering.

Structured interviews have assumed an increasingly prominent role in psychological assessment. They have standardized both the questioning and clinical ratings of psychological symptoms and associated features. For the assessment of feigning, the *Structured Interview of Reported Symptoms, Second Edition* utilizes eight distinct detection strategies to systematically distinguish between feigned and genuine clinical presentations. By applying a decision model, most examinees can be classified as displaying a feigned, questionable (i.e., not confidently interpreted as either feigning or genuine), or genuine presentation. An important goal of the *Structured Interview of Reported Symptoms, Second Edition* is to minimize false positives (i.e., misclassifying a genuine responder as a malingerer), which can have devastatingly negative effects in professional contexts such as forensic and correctional settings. The profoundly adverse consequences associated with misclassification may include potentially increased sentencing and limited treatment offerings.

Feigning measures must also address a further challenge; a presumably small percentage of malingerers prepare their simulated impairment by specifically researching and accessing information on how to outwit detection strategies. In some instances, this information is relayed to the examinee by others. Therefore, this use of information to foil detection strategies is referred to as *coaching*. For multiscale inventories, some feigning indicators have been shown to be more resistant to coaching than others. For the *Structured Interview of Reported Symptoms, Second Edition*, a countermeasure was introduced to detect sophisticated feigners who deny common psychological problems in their efforts to go undetected. Concerns about the impact of coaching again underscore the importance of comprehensive assessment utilizing well-validated detection strategies.

Future Directions

Future research will continue efforts for more precise classification of malingering and other response styles. It may be possible to identify what is feigned (e.g., post-traumatic stress disorder)

from what is not (e.g., underlying depression). This sophisticated approach would avoid the *all-or-none* perspective to clinical interventions whereby any feigning precludes all treatment. In addition, further education and training are needed to refute the common myths of malingering. As an example, clinicians who disavow the fallacy of “once a malingerer, always a malingerer” can more objectively evaluate current treatment needs without being unnecessarily biased by evidence of past feigning. More complex detection strategies, such as symptom combinations (i.e., identifying symptoms that are unlikely to co-occur) can be further refined to remain effective even with coached feigners.

MANDATORY MINIMUM SENTENCING

Mandatory minimum sentencing statutes specify that certain criminal offenses hold a particular sentence that must be adhered to without exception. For such offenses, judges specify the maximum term but cannot sentence the offender to less than the statutory minimum. Some mandatory minimum sentences restrict parole eligibility as well. Mandatory minimum sentences exist at both the state and federal levels and are most commonly applied to repeat or habitual offending, drunk driving offenses, drug offenses, weapon offenses, and sex offenses. These statutes significantly reduce judicial discretion by eliminating a judge's ability to take into account mitigating factors, such as past criminal history, instead by applying a one-size-fits-all approach to sentencing. After reviewing the history of mandatory minimum sentences, this entry discusses sentencing reform.

History

Until the 1970s, significant attention was paid to the rehabilitation of offenders, and indeterminate sentences, which gave judges wide discretion in sentencing, dominated criminal justice systems across the United States. However, growing disillusionment with the rehabilitative model of punishment, along with simultaneous increases in violent crime rates, resulted in a decidedly punitive turn. In 1973, New York became the first state to establish mandatory minimum sentences for drug offenses under New York's Rockefeller Drug Laws, with a number of states following suit. Policy makers claimed that mandatory minimum sentencing would both reduce judicial discretion and decrease disparities across sentences, while at the same time effectively reducing crime. Throughout the 1980s, legislatures used mandatory minimum sentencing as a primary tool to fight the War on Crime, with particular attention paid to gang and drug offenses. In 1986, the

Anti-Drug Abuse Act established mandatory minimum sentences for federal drug offenses and instituted the 100:1 powder-to-crack-cocaine sentencing ratio disparity. Mandatory sentencing provisions typically were enacted swiftly, with no evidence of effective crime reduction outcomes, and have dramatically increased the size of the U.S. prison population.

Mandatory minimum sentencing maintained popularity throughout the 1990s. However, by the end of the decade, concern over their detrimental effects began to grow. Now, mandatory minimum sentences are widely recognized as a primary driver of mass incarceration. A 2011 report published by the United States Sentencing Commission condemned mandatory minimum sentences, citing several consequences, including the following: (a) disproportionate burden on racial minorities and economically disadvantaged communities, (b) unjustified sentencing disparities between similar offenders, (c) unnecessarily harsh and arbitrary sentences that reach too broadly, and (d) a dramatic rise in prison population and cost.

Sentencing Reform

As early as 2000, states began reevaluating their use of mandatory minimum sentencing, with Michigan being the first state to eliminate mandatory minimum sentences in 2002. Since then, 29 states have taken steps to reduce or eliminate mandatory minimum sentences. At the federal level, there is now bipartisan support for consensus-driven sentencing and corrections reform with the goal of reducing prison overcrowding and establishing a more equitable punishment system. In 2006, the Bureau of Justice Assistance introduced the Justice Reinvestment Initiative aimed at improving the criminal justice system. The Fair Sentencing Act, passed by Congress in 2010, began to address racial disparities in crack-cocaine sentencing by reducing the amount that would trigger minimum sentencing from 100:1 to 18:1 and eliminating the 5-year minimum for first-time crack possession. Efforts to reduce the severity of mandatory minimum sentencing have already begun to shrink prison populations at both the state and federal levels.

Two bills first introduced during Barack Obama's presidency aimed at further reducing

mandatory minimum sentences at the federal level. The Justice Safety Valve Act of 2013 proposed a new *safety valve* that would apply broadly to *all* federal crimes that carry a mandatory minimum sentence. This would mean that, in some cases, judges would be allowed to impose a sentence less than the stated mandatory minimum. The Sentencing Reform and Corrections Act (SRCA) of 2015 proposed making revisions in the 2010 Fair Sentencing Act retroactive, as well as further reducing several other federal mandatory minimums for drug and gun offenses. Although fewer offenses would trigger a mandatory minimum sentence, the SRCA would not address the 5- to 10-year minimum sentences imposed on nearly half of all federal drug offenders. The SRCA also introduced a new mandatory minimum sentence that would impact a group not previously subjected to mandatory sentences: a 15- to 25-year minimum for federal drug offenders who have previously been convicted of a violent felony. However, the Justice Safety Valve Act and the SRCA were reintroduced in the 115th Congress (2017–2018), but as of September 2018, neither has been passed by the Congress.

Future Directions

As a result of mass incarceration, politicians are reevaluating the practices of the criminal justice system. Politicians on both sides of the political spectrum have supported the development of evidence-based policies that are both cost-effective and successful at reducing crime. While it may be difficult to predict the fate of mandatory sentencing at the federal level, the swing away from mandatory minimum sentences and toward alternative models of sentencing across many of the states is likely to continue as states continue to try to find ways to reduce prison populations without compromising public safety.

MARA SALVATRUCHA

The Mara Salvatrucha 13 gang was formed by Ernesto Miranda and Julio Cesar in 1980 as a means of defense against Los Angeles street gangs. Today, the Mara Salvatrucha 13 gang is known as the MS-13 gang and is recognized as a growing transnational, organized gang whose territory stretches across the United States and into Central America and is one of the most dangerous gangs in the United States.

The MS-13 gang name originates from the street La Mara in San Salvador and the Salvatrucha guerillas who fought in El Salvador's Civil War (1981–1992). During the Salvadorian Civil War, children as young as 14 years of age were inducted either into the Salvatrucha guerilla or government forces. Some of the children inducted into the Salvatrucha guerillas went on to establish the MS-13 gang. As of 2017, MS-13 is active in 42 U.S. states as well as El Salvador, Guatemala, Honduras, and Mexico.

Membership

When MS-13 was first established, membership was strictly limited to El Salvador, Ecuador, Mexico, Honduras, and Guatemalan citizens. Now, membership is open to all Latinos. Membership in MS-13 gangs is predominately men who range from ages 11 to 40 years. However, two key characteristics of MS-13 gang members are their ethnicity and all must speak Spanish. These two key characteristics help to ensure a sense of protection for the members because it lessens the chances for infiltration by other gangs and law enforcement officers. In some East Coast MS-13 groups,

females are permitted membership, but it is not common to see female members within the Los Angeles-based gang.

Unlike other Hispanic gangs, MS-13 members are spread across the entire United States, with the Southeast and Northeast regions seeing the greatest increase in memberships. MS-13 members have found that the best way to increase and maintain membership is through migration. When traveling to other areas or claiming new territory, MS-13 members prefer to openly show their colors (blue and white).

Similar to their desire to migrate, MS-13 gang members are also known for easily adapting to other avenues of criminal activity. Having a short learning curve for new tactics or situations allows the gang to quickly adapt to new conditions, opportunities, or threats.

Initiation, Recruitment, and Rules

To ensure that members are worthy of being an MS-13 gang member, prospective members are required to go through an initiation process. Male prospective members are beaten for a period of 13 seconds by current MS-13 gang members. Prospective female members are either beaten by or have sex with a current MS-13 gang member. Once an individual becomes a member of the MS-13 gang, he or she is required to adhere to the gang's "*code of silence*." Refusal of orders handed out or missing a gang meeting is not allowed unless given permission by that specific MS-13 gang boss. Those caught breaking the MS-13 code of silence or working undercover as an informant for other gangs or law enforcement will be murdered. In the eyes of MS-13 members, membership is for life and the members of that MS-13 gang are an individual's family.

One method that is commonly used to recruit new MS-13 gang members is recreational activities, such as soccer games. Hosting soccer games provides many benefits to MS-13 gang members as it allows them to seek out prospective members while appearing prosocial around locals. By engaging in "*normal*" social activities, MS-13 seems less of a threat and more a part of the community, allowing them to use these activities as a cover for their criminal actions.

Organizational Structure

Within the MS-13 gang, structure is crucial; however, the organizational structure differs from region to region. Within each MS-13 gang are various cliques that run independently. Over each of these cliques is the "*shot caller*," or the gang boss. The next most important person in the MS-13 gangs are the "*runners*"—messengers who travel between each clique delivering messages either from one clique to another or from the shot caller or the boss. Typically, the position of shot caller is assumed by a "*strong man*" and is not a democratic process.

Common Crimes

MS-13 gang members' criminal activities are split into two groups referred to as *primary and secondary crimes*. Primary crimes are crimes that generate money, and secondary crimes are crimes that are committed in support of primary crimes. Primary crimes include, but are not limited to, drug trafficking, smuggling of weapons, carjacking, extortion, human trafficking, theft, robbery, and prostitution. As for secondary crimes, MS-13 gang members have been reported to have participated in murder, assaults, and gang rapes. The trademarks of most MS-13 gangs are drug rip-offs and raids on opposing gang members' houses. All raids conducted by MS-13 gangs are led by an individual who is well trained in paramilitary tactics. These tactics include perimeter lookouts, high-powered weaponry use, and precise room-by-room searches.

Violence

Violence is an expected part of gang life, but MS-13 violent activity is unique due to the manner in which members engage. Within all MS-13 gangs, there is a strict set of rules detailing when a member can kill and how the member can kill a victim. Members are granted permission to kill when the boss or shot caller issues a "*green light*." When a member is assigned an assassination, the member is under strict orders to shoot the victim only in the head. If a member is unsuccessful in producing a head shot during the assignment, that individual will be penalized. One trademark of an

MS-13 assassination is that the assigned gang member will typically leave a death note on the body of the victim, detailing why the individual was murdered, which serves as a warning to other gangs and government officials.

MS-13 Identification

The MS-13 gang colors are those of the Salvadorian flag: blue and white. Members use the numbers 13, 67, or 76 to identify with their specific gang. The numbers 67 and 76 are sometimes used as code because when added together $6 + 7$ equal 13. MS-13 gang members are also notorious for their use of tattoos to communicate their loyalty and their involvement in gang and prison activity. Some of the tattoos that gang members are commonly found sporting include letters, tear drops, bricks, comedy and tragedy masks, crossbones, and daggers. The comedy and tragedy masks represent the message of laugh now, cry later. Three tear drops tattooed on a gang member's face are meant to show respect to a fallen gang member. Tattoos of bricks represent the number of years an individual served time in prison. Each MS-13 gang across the country has its own meanings behind the tattoos. On the East Coast of the United States, members are known for sticking to Mayan traditions and may tattoo their entire body, including their face. Besides tattoos, MS-13 members are also fond of heart-shaped jewelry and wearing rosaries that are either blue or white. Similar to other gangs, MS-13 gangs are also known to use graffiti to mark turf, spread messages, or to show respect to fallen gang members.

Response to MS-13 Gangs

Some MS-13 gang members are in the United States illegally. Although deportation is used as a means of decreasing illegal immigrants, it may also be used in an effort to decrease membership in gangs, such as MS-13. However, in the case of MS-13, instead of decreasing membership, deportation has actually helped to increase MS-13 gang membership. Consider instances in which gang members of Salvadorian descent are deported back to El Salvador, which is one of the recruiting countries for membership in MS-13. In El Salvador, prison conditions are very poor, and the

prison guards are easily corrupted. In addition, youth in El Salvador tend to idolize MS-13 gang members from Los Angeles. Thus, gangs members may see deportation as an opportunity for recruitment, drug or weapon smuggling, and re-connecting with friends and family members. Upon arrival in the home country, such gang members form new cliques of the gang in their home country.

MS-13 Gang Members in Their Home Countries

It has been estimated that as of 2017 there are at least 22,000 MS-13 gang members in El Salvador. One of the most difficult tasks for Salvadorian authorities is identifying MS-13 gang leaders. It is rumored that the gang leader of the El Salvadorian MS-13 gang is in prison and continues to make decisions and distribute orders to other gang members. As the activities of Salvadorian MS-13 gang members become more sophisticated, catching and bringing them in are also proving difficult for authorities.

Crime rates in Guatemala are similar to those in El Salvador. Guatemalan authorities estimate that as of 2017 there are around 3,000 MS-13 gang members and 200 gangs active in Guatemala. Capturing gang members in Guatemala is complicated by its proximity to Mexico, as after committing a crime gang members often flee into Mexico. Guatemalan prisons also may serve as breeding and training grounds for future and current MS-13 gang members.

Honduras has also become a place of refuge for Salvadorian and Guatemalan refugees, as well as a place for forming new MS-13 gangs. In 2017, gang membership in Honduras is estimated to be about 60,000. Some MS-13 gang members have been hired as soldiers to distribute drugs and weapons, perform executions, or provide distractions for law enforcement while gang business is occurring. However, in contrast to other countries where MS-13 is active, Honduras is determinedly fighting back against gang activities. The Honduran president's son was killed by a MS-13 gang member in 1997, and as a result, Honduras has enacted tougher laws aimed at curtailing gang activity. One example is the length of prison sentence for MS-13 gang members whereby members who have held a leadership position receive 12-year sentences, and other gang members receive

9-year sentences. In response to recently enacted laws, some MS-13 gang members have fled back to El Salvador or to the United States.

In Mexico, unlike other gangs that have tried to compete with Mexican drug manufacturing and trafficking organizations, MS-13 has created an alliance with them. Together, the two gangs create a team whereby the drug trafficking organizations manufacture the drugs and MS-13 gang members ship, distribute, and merchandize the drugs.

MS-13 Allies and Enemies

Similar to other gangs, MS-13 has its own allies and enemies. Some of its allies include SUR 13, LA Gran Familia, Southwest Cholos, Hell Angels, El Chapo, and Los Zetas. The MS-13's enemies include the Latin Kings, Brown Pride, LA 18, Gangster Disciples, La Raza, and the United Blood Nation.

MASS INCARCERATION

See Community Context and Mass Incarceration

MASSACHUSETTS YOUTH SCREENING INSTRUMENT

The Massachusetts Youth Screening Instrument (MAYSI) was developed in the 1990s by Thomas Grisso and Richard Barnum at the University of

Massachusetts Medical School with grants from the William T. Grant Foundation and the MacArthur Foundation. It was designed to be used within the juvenile justice system to identify youths experiencing thoughts, feelings, or behaviors that may need immediate attention regarding possible suicide risk or emergent mental health needs. Since being made available in 2000, the second version, MAYSI-2, has been adopted by over 1,500 juvenile justice facilities in 48 U.S. states to screen youths' mental health needs when entering those facilities. This entry focuses on the development of, research behind, and use of the MAYSI-2 within the juvenile justice system.

Basic Description

The MAYSI-2 was designed to assist juvenile justice agencies in identifying youth who have mental health and emotional needs. It is not intended to provide psychiatric diagnoses. It is intended for use at a youth's entry or transitional placement points within the juvenile justice system. The MAYSI-2 was designed to be a brief, self-report screening tool that consists of 52 questions written at a fifth-grade reading level. Youths circle *yes* or *no* concerning whether each item has been true for them *within the past few months* or *ever in your whole life*. There are six primary clinical scales: Alcohol/Drug Use, Angry-Irritable, Depressed-Anxious, Somatic Complaints, Suicide Ideation, and Thought Disturbances (boys only). A seventh nonclinical scale, Traumatic Experiences, provides information about potential recent trauma.

The MAYSI-2 can be administered in two ways: (1) youths read the items themselves or have juvenile justice staff read them the questions on the paper-and-pencil version or (2) youths use the computerized version of the MAYSI-2, known as MAYSIWARE (or an equivalent provided by a commercial online assessment service), whereby they are read the items via the computerized voice program while responding to the questions using the keyboard or mouse. MAYSIWARE is available in both English and Spanish, and the paper-and-pencil format is available in English, Spanish, and 15 other languages.

Youths' *yes* answers are summed for each scale either by use of a scoring key if the paper-and-pencil version is administered or automatically if

MAYSIWARE is used. The scores are then recorded on the Scoring Summary Form. Youths' answers contribute to seven scales for boys and six scales for girls, each scale having 5–9 items. The six clinical scales were developed with two levels of cutoff scores, which are used to define what is meant by a *high score* on any scale: *Caution* and *Warning*. Scores above the Caution cutoff indicate that the youth scored at a clinical level of significance, meaning the youth may be in need of some clinical, nonurgent, attention. Scores above the Warning cutoff indicate that a youth has scored in the top 10% of youth in the normative sample on a given scale, meaning the youth scored exceptionally high in comparison to other youths in the juvenile justice system and is potentially in need of an immediate emergency response. Normative sample refers to the sample of test takers representative of the population for whom the test is intended. The MAYSI-2's normative sample is youths involved in the juvenile justice system (probation intake, detention, and corrections).

Development of the MAYSI-2

Initial item development for the six MAYSI clinical scales involved a review of the symptoms of the more prevalent mental disorders, emotional disturbances, and behavioral problems among adolescents. The wording of the 52 items was guided by consultation with national experts and in consultation with youths in the Massachusetts Department of Youth Services to determine any difficulties in understanding the words or phrases comprising each item. The following chronology shows the initial development, testing, and subsequent revision of the original MAYSI:

1994–1996: Initial drafting and pilot testing of the MAYSI.

1996–1998: Scales identified, initial norms and cutoffs developed, and initial validation.

1998–2000: Additional analyses of the Massachusetts data lead to the second version of the screening tool (called the MAYSI-2) and a new manual.

2000–2002: The MAYSI-2 released to juvenile justice agencies and, with funding from the MacArthur Foundation, the National Youth Screening &

Assessment Program developed to provide technical assistance to those agencies using the MAYSI-2.

2002–2005: National norms developed using data collected from over 70,000 juvenile justice agencies (intake probation, detention, and corrections) and MAYSIWARE developed. Evaluation of the impact of mental health screening in juvenile justice settings conducted with funding from the William T. Grant Foundation. In addition, how the MAYSI-2 was being implemented nationally and its effect on youths' mental health services in juvenile justice settings evaluated with funding from the MacArthur Foundation.

2005–2011: Technical assistance for MacArthur Foundation's *Models for Change* Initiative provided.

2011–2015: Technical assistance to jurisdictions and states that are using or plan to use MAYSI-2/MAYSIWARE provided.

Research Evidence

In 1994, after a review of symptoms associated with prevalent mental disorders, emotional disturbances, and behavioral problems among adolescents, 52 questions were selected to create a MAYSI questionnaire prototype. During the next few years, efforts began to identify the scales, develop norms and cutoff scores, and determine psychometric properties. Which of the original 52 items would be included was determined through a process of examining a series of analyses including item total correlations, α coefficients, and factor analyses. Factor analyses performed on a Massachusetts sample led to decisions about the final scales and their items. Additional analyses were subsequently performed on another sample of youth from California, confirming the Massachusetts results. Finally, the performance of youths taking both the MAYSI-2 and other validated scales of child psychopathology were used to determine the cutoff scores on the six clinical MAYSI-2 scales.

In 2005, a study was conducted with a national sample of youths in juvenile justice facilities in 19 states. This research allowed MAYSI-2 users to compare youths to national norms rather than the Massachusetts norms on which the original cutoff scores were based and examined the degree of consistency across age, gender, and race-related

differences in the proportions of youths with elevated MAYSI-2 scales.

To measure the internal consistency of the MAYSI-2, researchers used Cronbach's α coefficients, which ranged from .61 to .86 for items within scales, indicating acceptable internal consistency. Few differences were seen in α coefficients between race and gender. The MAYSI-2 has also been shown to be reliable (using intraclass correlation coefficients) based on comparisons of individual youth scores across a 1- to 2-week period of time, ranging from .53 to .89 across various scales. Analyses aimed at addressing MAYSI-2's validity showed that the MAYSI-2 scales correlated in the expected direction, with scales measuring parallel symptom constructs on other mental health assessment instruments.

Since made available in 2000, numerous studies and reviews have examined the reliability, internal consistency, utility, and structure of the MAYSI-2. A detailed review of the existing research in addition to up-to-date quarterly reviews of MAYSI-2 research can be found on the website of the National Youth Screening and Assessment Partners. The reviews present research only when the MAYSI-2 was used in the settings for which it was intended, on the target populations for which it was developed, and administered in the manner recommended by the authors.

Use of MAYSI-2 in Juvenile Justice Facilitates

The MAYSI-2 is the most widely used mental health screening tool in juvenile justice facilities, and it is recommended by a number of U.S. government juvenile justice and mental health agencies. Its values and limits are identified by over 60 published studies in scientific journals.

With a little more than one half of young people entering juvenile justice facilities meeting criteria for one or more mental disorders, the MAYSI-2 provides a quick way to identify mental health and substance use symptoms that may threaten the welfare of youth. For example, the MAYSI-2 can help determine if an immediate (acute) emergency response is needed to suicide risks or to youths who may need immediate attention due to an acute condition that may deteriorate rapidly (e.g., substance abuse withdrawal). The MAYSI-2 can also help

alert staff to the potential need for longer range rehabilitation plans by identifying youths whose chronic and persistent mental health problems may need care on a continuous basis. In addition, it can aid in identifying conditions (e.g., depression) that may increase the risk of aggression, which could put staff and other youth at risk.

MAYSI-2 scores are used to determine whether a youth is *screened out* (i.e., needs no further follow-up or assessment) or *screened in* (i.e., requires a staff follow-up response and/or further mental health assessment). *Screened in* means the youth's scores are above the Caution or Warning cutoffs on any of the six MAYSI clinical scales. The clinical scales and cutoffs that define *screened in* are determined as a matter of policy by an agency's administrators and, therefore, may be different between jurisdictions across the United States.

The types of follow-up responses when a youth is screened in include having staff ask second screening questions, which are available for each of the six clinical scales comprising the MAYSI-2. The second screening questions allow staff to rule out false positives and determine a course of action (e.g., obtain an emergency clinical assessment for the youth, schedule a nonemergency comprehensive assessment for the youth, refer the youth to a mental health diversion option).

As with all screening tools, the MAYSI-2 does not provide psychiatric diagnoses, and the cutoff scores do not identify every youth who might have a mental disorder nor do they assure that all youths *screened in* actually have a mental disorder. Also it does not provide the type of information needed to make long-range treatment plans. In addition, some scores above the cutoff are temporary moods, while others are due to longer term conditions. Therefore, this type of intake screening should be used only for intake management and should not be used for longer term planning (e.g., case dispositions). Lastly, the MAYSI-2 does not protect against self-report bias, so youths may sometimes conceal symptoms, and they may sometimes exaggerate them.

Research suggests that there are no differences in MAYSI-2 scores for paper-and-pencil administration versus computer administration (via MAYSIWARE), although youths tend to prefer the computer to paper-and-pencil, and when youths need to have the items read to them (e.g., because

of reading problems), they tend to report more freely to the computer administration (whereby the items are read to the youth via computerized voice program) than to a staff member reading the items to them.

Screening for mental health needs using the MAYSI-2 with youth in juvenile justice settings has become standard practice nationwide—at probation intake, detention centers, or juvenile corrections programs. Identifying young people's needs—substance use, trauma-related problems, and suicide ideation—is important at first contact. It is the first step for identifying those who need immediate attention and further assessment for mental health needs.

Special initiatives are being developed to study and improve mental health screening in juvenile justice facilities in other countries. Researchers in 17 countries covering Asia, Australia, Europe, the Soviet Union, and the Americas have translated the MAYSI-2 into various languages in order to conduct further research on the cross-national and cross-cultural effectiveness of implementing juvenile justice mental health screening, using the MAYSI-2.

MATCHING TREATMENT BY OFFENDER TYPE AND THERAPIST STYLE

The general question of *what works* in offender treatment has led to numerous research studies, reviews of the literature, and clinical reflection. Over time, interventions have been modified and enhanced to increase effectiveness. Various meta-analyses have been conducted that have evidenced that certain types of treatment are more effective than others. Currently, more complex questions are being explored; that is, what types of intervention are more effective, under what circumstances, and with whom?

Both the general clinical literature and offender literature have explored specific factors that are thought to impact treatment effectiveness. There are a wide range of issues to explore, including therapist factors, client factors, treatment orientation (e.g., cognitive behavioral therapy [CBT], psychodynamic, interpersonal), group versus individual intervention, as well as factors completely external to the process, which are more difficult to identify.

The purpose of this entry is to explore each of these issues, as a means of identifying the optimal approach therapists can use when working with offender clients. The challenge is that there is no one method or approach that will be effective with everyone; however, there are some common factors that underlie good intervention and can allow therapists to tailor their intervention to better meet the needs of each individual client.

Risk, Need, and Responsivity

One well-known approach to determining treatment for offenders is Don Andrews and James Bonta's Risk-Need-Responsivity model. According to the risk principle, the intensity of intervention should vary based on the risk level of the individual. From this perspective, higher risk

offenders should be provided with more intensive services, while lower risk offenders should be provided with low intensity or no services.

Based on the need principle, treatment providers should focus on criminogenic needs that are relevant to the individual—for example, attitudes or beliefs supportive of crime, negative attitudes toward women, or sexualized views of children. Researchers suggest that there are stable dynamic needs, such as attitudes, and more acute needs, such as anger or intoxication. Therapists can work directly with clients to identify their personal needs; some may be common across groups; for example, sexual offenders often struggle with sexual interests/sexual self-regulation, distorted attitudes, intimacy deficits, and self-regulation problems. However, the intervention strategies will differ as some needs may be more pressing than others, and clients will respond differently to different interventions. Some argue that needs that are not criminogenic (e.g., self-esteem) should therefore not be targeted as these factors have nothing to do with recidivism. Others argue that while trying to address every need area is likely not necessary, especially when time and resources are limited, some noncriminogenic needs are responsivity factors that should be targeted to enhance treatment gains (e.g., low self-worth often inhibits one's ability to change).

Often the least considered principle, yet no less important, is the responsivity principle. According to this principle, the treatment approach and techniques should be tailored to meet the learning style and abilities of the offender. However, the responsivity factor is often ignored, especially in standard treatment programs. Offender clients may struggle in some domains; they may be diagnosed with or experience symptoms of attention-deficit/hyperactivity disorder, low cognitive functioning, or a major mental illness. All of these issues require some form of accommodation to their interventions. Furthermore, individual clients respond to different activities. Some clients may enjoy reading self-help or complex books, whereas other clients may not do written homework or only remain in session for a short period of time. Such individual responsivity factors will be explored in more detail throughout this entry.

Therapeutic Process and Treatment Outcome

The client–therapist relationship has received significant attention in the general clinical literature; the quality of this relationship is considered to be more relevant to treatment outcome than the particular techniques used by the therapist. The quality of this relationship is impacted by therapist characteristics such as empathy, warmth, genuineness, respectfulness, supportiveness, emotional responsivity, directiveness, flexibility, and interest in the client. Characteristics that impede change include confrontation, anger, and rejection. Failure to establish an alliance can lead to treatment noncompliance and poor outcomes.

Based on the research literature, when therapists are confrontational, defensive, and inconsistent, offenders are more likely to drop out of treatment, whereas when therapists are supportive, empathic, warm, and genuine, offenders tend to remain in treatment and meet their treatment goals. It has also been found that offenders are less likely to engage in treatment when they believe that treatment will focus only on their offending behavior rather than focusing on helping them improve themselves and their lives overall. Therefore, the literature supports adopting a motivational approach.

Therapist Factors

Various researchers in the general psychotherapy literature have explored whether therapist factors such as age, gender, ethnicity, or religion have an impact on treatment effectiveness. Ethnicity has been explored extensively, as there appears to be a belief that ethnic matching leads to more effective intervention. Interestingly, although there is variability, most meta-analyses find that while clients often prefer a therapist who is the same race or culture, there is minimal impact on effectiveness. Factors such as gender, age, or religion have no real impact.

Where the therapist impact lies is with respect to therapist characteristics (e.g., empathy, warmth, genuineness). The general psychotherapeutic literature is extensive, and much research has been generated demonstrating the value of therapist qualities; however, some research has focused

specifically on therapist qualities. In such research, the researchers viewed video-recorded sessions and rated the degree to which various therapist qualities were displayed. Qualities such as warmth, empathy, directiveness, use of self-disclosure, confrontation, and genuineness were explored. It was found that therapists who are warm, genuine, empathic, and moderately directive were the most effective at eliciting change in domains such as attitudes and coping skills. Therapists who displayed an aggressively confrontational approach were found to have a harmful effect on clients. This counters the belief that offender clients should be harshly challenged on their behavior. What appears to be most effective is to establish a strong therapeutic alliance that occurs when one possesses qualities such as warmth and empathy; then therapists can challenge clients in a direct, supportive manner that elicits change.

Client Factors

Psychopathy

It is a popular conception that psychopaths are high risk and cannot be effectively treated. Some earlier research with psychopathic sexual offenders supported the notion that treatment made them worse. However, later analyses suggest that psychopathy is a responsivity factor, that psychopaths can in fact develop a therapeutic alliance and therefore can be effective treatment participants. Developing a rapport with these challenging clients, providing them with concrete feedback, and focusing on criminogenic and interpersonal domains are helpful in working with this client group.

Motivation

Since noncompletion of treatment is associated with recidivism among all types of offenders (domestic violence, sexual offender, general offending), engagement and motivation are key issues that should be considered in offender treatment. So, what factors increase motivation for change and engagement? According to the transtheoretical model of change, treatment interventions should be matched to the offender's stage of change. For example, offenders in the precontemplation stage of change would be considered unmotivated and less likely to engage in treatment. Reviews of the literature indicate that

demographic and historical factors are not particularly relevant but that factors such as hostility, impulsivity, and psychopathy create behaviors that can be difficult to control and manage in intervention programs. It has been argued that the therapeutic relationship promotes success at each stage of engagement. However, it is often more difficult for therapists to work with clients who are hostile, impulsive, or display psychopathic traits. Therapists with excellent interpersonal skills and a warm, empathic yet appropriately directive nature would be best matched with these difficult clients.

Treatment Approach

Orientation

CBT has typically been put forward, in the offender literature, as the preferred therapeutic orientation. Therefore, most programs are delivered from a CBT style. However, CBT is also likely the most empirically researched orientation, and while effective, other orientations cannot be discounted. For example, Marsha Linehan's dialectical behavior therapy has been demonstrated effective in working with borderline personality disordered clients, with some limited research demonstrating that this approach is effective with offenders as well. The Rockwood Psychological Services approach to group therapy with sexual offenders is process oriented in nature, integrating CBT, dialectical behavior therapy, interpersonal, emotion-focused, and attachment-based interventions with a strong emphasis on the development of the therapeutic relationship. This program has demonstrated efficacy in reducing recidivism.

Therefore, it should not be assumed that only one treatment orientation should be used in all instances. For some clients, especially those who are demonstrating problematic thinking patterns, cognitive behavioral strategies can help them to modify their thoughts and think more flexibly. Other clients require more mindfulness-based or emotion-focused techniques, especially if they struggle with attachment-based issues.

Manualized Programs

In conducting treatment with offenders, a flexible approach is encouraged. Highly detailed treatment

manuals or a solely psychoeducational approach to intervention is contraindicated; adopting a comprehensive treatment approach is more likely to help individuals who have offended better integrate and accept change on an emotional level. While there is an argument that treatment manuals are necessary to ensure consistency and treatment integrity, following a manual too closely can result in a rigid approach that discourages clients from addressing relevant issues *in the moment*.

Without a flexible approach, treatment may become more *one size fits all*, and the integration of personal connections, emotional connection to the material, or real change may be compromised. Flexibility on the part of the therapist therefore enhances the therapist's ability to ensure that he or she is meeting the needs of the client.

Group Versus Individual Intervention

There has been much debate as to whether group or individual intervention is preferable when working with offender clients. Essentially, both approaches have demonstrated effectiveness. Group intervention is typically preferred because of practicality and cost-effectiveness. With limited resources, addressing issues in group can target a larger number of clients, and in both the general therapeutic and offender literature, there is a strong value to group cohesion. Although either modality can be quite effective, therapists should ensure that process issues are considered, flexibility is adopted, and the Risk-Need-Responsivity principle is applied. With respect to matching for client needs, a therapist might provide individual treatment if a client has lower functioning or has a difficult time integrating concepts in group. With respect to group intervention, therapists need to remember that clients will respond and integrate material in different ways and should not assume that everybody will work at the same pace.

Conclusions and Recommendations

If one were to identify the perfect circumstances for matching offender and treatment approach, they would include the following: a highly motivated client working with a positive and motivational therapist, at an intensity level that matches the offender's risk and need, and who also accounts for individual responsivity factors. It is known

from the literature that to maximize treatment effectiveness, there needs to be a strong therapeutic alliance, and to develop this alliance, the therapist needs to display positive therapeutic characteristics and be firm yet supportive rather than confrontational when challenging inappropriate attitudes or behaviors. In the case of more challenging clients, such as hostile, impulsive, or psychopathic clients, the therapist needs to be even more motivational and display therapeutic characteristics to an even higher degree.

Based on the literature, therapists who choose to provide treatment to offenders should be positive, supportive, and motivational; they should have a good understanding of the literature about *what works* and should be flexible and able to work with clients at different levels of motivation, intellectual capability, risk level, and need.

MEASUREMENTS AND SCALES, USE IN FORENSIC RESEARCH

A variety of assessment measures and scales are used in forensic research. Research concerning forensic assessment is particularly relevant to the legal system. Judges rely on the opinions of experts regarding acceptability and accuracy of measurements in order to make decisions such as admissibility of evidence (see *Daubert v. Merrell Dow Pharmaceuticals, Inc.*, 509 U.S. 579 (1993)). Forensic assessment research focuses on creating valid and reliable measurements of constructs relevant to the court system, including competency, mental status, and risk. Therefore, there is little distinction between the use of measures in forensic research and in forensic practice, with the goal of much research being to improve measurement in practice. There are many different applications of forensic assessment (ranging from diverse applications such as parole evaluations, child custody evaluations, or personal injury law), and this entry describes just a few of the applications and measures most commonly encountered in the justice system.

Important Properties of Psychological Measures

To be useful, psychological measures must possess certain characteristics (often called *psychometric* characteristics) that serve as standards of quality for these measures. Among these properties is *standardization*, which attempts to ensure that the measure is applied the same way to all individuals being measured. Part of the process of standardization involves obtaining *norms* or information about the typical scores on the measure in the population of interest. Norms are necessary to characterize an individual's score as *high* or *low* because such statements are made relative to typical performance on the measure.

Another key concept is *reliability*, which describes the extent to which a measure yields consistent scores. There are different types of reliability—for example, researchers can test whether individuals obtain the same scores on a measure administered twice on consecutive days, which would be *test–retest reliability*, and researchers can also evaluate rating scales for *interrater reliability* to determine whether two different raters will arrive at the same score for a given individual.

Finally, *validity* describes the extent to which the measure actually measures the concept of interest. Validity is examined in a number of different ways—for example, *predictive validity* exists when a measure can successfully predict some criterion or outcome in the future. For example, a measure that can successfully predict parole violations when given prior to a parole hearing has predictive validity for this application.

These concepts are key issues for any psychological measure, and much research in forensic assessment involved evaluating these properties for the types of measures described in the following sections.

Forensic Applications of Measures and Scales

Evaluators use forensic assessment tools to measure relevant legal and psychological constructs in order to assist the adjudicator in answering legal questions. The most common applications of forensic measurement are evaluation of competency to stand trial, mental state of the accused at the time of the offense, risk of future violence, and evaluations of response style (e.g., malingering, such as faking or denying the presence of a mental disorder). Forensic measures and scales can be grouped into common content areas. General clinical assessment inventories may be used to examine response style, cognitive ability, and mental state at the time of offense. Forensic assessment inventories are measures that directly assess legal questions, such as risk of violence or competence to stand trial.

Examination of mental state at the time of the offense may involve the use of cognitive and neuropsychological measures, forensic assessment measures, and multiscale inventories. Determination

of risk typically uses forensic assessment measures as well as clinical inventories. The remainder of this entry provides examples of commonly used measures and their applications.

Risk Assessment and Psychopathy

Risk assessments are used to estimate the likelihood of future violent behavior within a specific time frame. Risk assessments may be used to determine sentencing, civil commitment, or parole eligibility. Commonly used measures in this area include those discussed in the following subsections.

Psychopathy Checklist-Revised (PCL-R)

The PCL-R is a 20-item rating scale measure used to assess for the presence of psychopathy. It is scored based on the completion of a clinical interview and a review of institutional records such as arrest reports or corrections documents; because of the importance of such records in arriving at PCL-R ratings, problems can occur when there is limited historical file information available to the evaluator. Although its primary use in research is to diagnose psychopathy, the PCL-R is also commonly used for risk assessment to predict criminal reoffending and response to treatment. Numerous studies indicate that the PCL-R can validly predict important factors such as risk of reoffense or institutional misconduct. However, there is some controversy as to whether its predictive validity mainly comes from its characterization of previous criminal offending rather than from an assessment of the individual's psychological makeup at the time of the evaluation. In addition, though the PCL-R demonstrates acceptable interrater reliability in research settings, multiple studies have suggested that field reliability between raters, particularly in adversarial legal proceedings, is considerably lower.

Historical Clinical Risk Management-20 (HCR-20)

HCR-20 is a 20-item risk assessment measure that identifies past, present, and future markers of risk. It was designed to be easy to use, as it does not rely on complex scoring schemes. Rather, based on the structured professional judgment

approach to risk assessment, the HCR-20 places individuals in low-, moderate-, or high-risk categories. The measure was developed by researching factors related to violence. The HCR-20 demonstrates good interrater reliability, meaning that raters provide highly similar risk judgments on the same individuals. The measure and each of its risk factors have also been found to predict future violence, indicating good predictive validity.

Violence Risk Appraisal Guide (VRAG)

VRAG is a 12-item actuarial scale that uses an individual's clinical record for determining future risk, examining factors such as elementary school maladjustment, diagnosis of a personality disorder, and failure on a prior conditional release. The measure was created by studying patterns of reoffense for more than 600 violent offenders. The VRAG provides the evaluator with an estimate of how an offender's risk compares to other individuals, based on their conviction or release setting. Research concerning the VRAG reports validity for predicting future violence in a variety of settings and for several types of violence. However, in some studies, the VRAG has been found to predict institutional misconduct for male but not female inmates.

Competency Evaluations

Forensic evaluators may be asked to assist in determination of both competency of the accused to waive *Miranda* rights and to stand trial. A survey of practicing forensic psychologists reported that the Wechsler Scales (described in a later section) and the MacArthur Competence Assessment Tool are most commonly used in determining competency.

MacArthur Competence Assessment Tool-Criminal Category Adjudication

The MacArthur Competence Assessment Tool-Criminal Category Adjudication was created to limit the influence of interviewer subjectivity in determining competency to stand trial. It consists of 22 items that inform the different competency requirements outlined in *Dusky v. United States*, 362 U.S. 402 (1960). The *understanding* measure

asks questions regarding the factual understanding of legal proceedings. The *appreciation* measure queries the respondent about his or her expectations regarding the respondent's case. Finally, the *reasoning* measure was created to determine the ability of the respondent to assist in his or her legal defense. Numerous studies have determined that the MacArthur Competence Assessment Tool–Criminal Category Adjudication demonstrates high interrater reliability and that the different items related consistently to each other (a form of reliability known as *internal consistency*).

Cognitive and Neuropsychological Measures

Although the following measures have many uses, only their applications to forensic assessment are discussed here. Cognitive and neuropsychological tests are sometimes used to determine mental status at time of the offense, competency to stand trial, and *Miranda* waiver evaluations. Intelligence tests can also be used in sentencing determinations; for example, in *Atkins v. Virginia*, 536 U.S. 304 (2002), the Supreme Court exempted those with *mental retardation* from the death penalty. The various Wechsler Scales are the most widely used cognitive measures for such purposes, although forensic evaluators report that the Stanford–Binet–Revised intelligence test and the Halstead–Reitan and Luria–Nebraska neuropsychological batteries are also acceptable for use in certain determinations.

Wechsler Scales

The Wechsler intelligence scales, particularly the Wechsler Adult Intelligence Scale–IV, are used across a wide variety of evaluations, including child custody, criminal responsibility evaluations, and competency to stand trial. The Wechsler Adult Intelligence Scale–IV provides evaluators with a Full Scale Intelligence Quotient as well as indices measuring verbal comprehension, working memory, perceptual reasoning, and processing speed; these scores tend to show very high test–retest and good interrater reliability. The Wechsler Individual Achievement Test–Third Edition measures academic achievement in a variety of areas such as reading comprehension and is often used to help

determine whether an individual is capable of participating in his or her own defense, for example, in reading court documents. Along similar lines, the Wide Range Achievement Test is also commonly used for similar purposes. The Wide Range Achievement Test measures an individual's ability to read words, spell, solve math problems, and comprehend sentences and is therefore relevant to questions of intellectual disability and competency.

Multiscale Inventories

Multiscale inventories are clinical questionnaires that each measure a variety of different mental health characteristics that are relevant to decision-making in forensic and treatment settings. These questionnaires are often called *objective tests* in that each respondent is asked precisely the same questions in the same order, scored in the same manner for all respondents, and each respondent's responses are compared to population norms. Because these questionnaires rely on the self-report of the respondent, many multiscale inventories include validity scales designed to evaluate the quality of the information provided by the respondent. For example, in some forensic settings, respondents might attempt to deny existence of any problems (e.g., in a child custody case, in a parole evaluation), while in other settings, they might be motivated to feign problems that do not exist (e.g., in an insanity hearing, in a transfer request to a lower security mental health unit). Validity scales can assist the examiner in identifying the presence of such *response sets* and evaluating their impact on the information provided by the respondent. The two multiscale inventories described in the following subsections are among the most commonly used measures in forensic settings.

Minnesota Multiphasic Personality Inventory-2 (MMPI-2)

The original MMPI was developed in the late 1930s with the goal of assisting mental health professionals in the diagnosis of mental disorders, and a revision of the instrument that included updated norms was completed in 1989. The 567 questionnaire items of the second version, MMPI-2, provide scores on 10 clinical scales that assess mental health

issues such as depression, paranoia, and schizophrenia. In addition, a number of validity scales are provided to identify response sets such as malingering, defensiveness, or inattentive responding. The MMPI-2 has been the focus of considerable research in clinical settings and has many applications in forensic settings; in particular, it has demonstrated considerable success in identifying symptom over-reporting in various forensic settings.

Personality Assessment Inventory (PAI)

The PAI was published in 1991 as a multiscale inventory designed to provide psychological assessment information pertaining to psychopathology, personality, psychosocial environment, and treatment planning. The 344 questionnaire items provide scores on 11 clinical scales measuring mental health concepts such as depression, anxiety, schizophrenia, and borderline and antisocial personalities. In addition, there are treatment consideration scales designed to assess important concepts such as aggressiveness, suicidality, and motivation for treatment. Finally, there are also a number of validity scales designed to measure response sets such as defensiveness, malingering, or inattentive responding. The PAI has been the focus of extensive research in forensic settings, and various scales have been found to have validity for predicting behaviors such as recidivism, suicidal behavior, and aggressive disciplinary infractions in correctional settings. In addition, the validity scales of the PAI have been found to be effective in distinguishing between different types of response sets, ranging from efforts to simulate schizophrenia to attempts to hide substance abuse problems.

MEDIA: INFLUENCE ON CRIME

Media, as a word, encompasses any number of forms of communication between groups and individuals, including books, newspapers, magazines, pamphlets, radio broadcasts, television broadcasts, and information and discussion posted on the Internet for public consumption and debate. Many forms of media are sponsored in large part by corporations with an interest in selling this information to consumers, either directly or through paid advertisements making the content more affordable to the public. The media exists to spread information and has led to an attachment to information by consumers that allows sponsors of media content to engage more consumers than the sponsors of other content, which often means a leading story in the media will be related to a topic about which many people have an opinion. Crime is one such topic. Crime and media have existed hand in hand for much of history and share an interesting relationship with one another, acting as influences on the other, sometimes spurring one another onward, even as they both possibly contribute to the influence of the media's public consumers and, at times, the use of forms of media to enable criminal activity itself.

A Brief History of the Linkage of Crime and Media

There is an adage, whose origin has been debated, in regard to the relationship between crime and

the media, “if it bleeds, it leads.” This phrase quite simply sums up the nature of news corporations of many forms to use the most shocking of criminal headlines to draw in readers or viewers in greater numbers. This works in large part because the sensation and a desire to know details of what is happening drive individuals to buy more newspapers, watch more television, or click more links.

The idea that sensationalism about crime will attract attention is an old one, and an individual need look no further into the past than the 1800s for this to become readily available. Public executions were often the sites of great congregations of people, a peculiar interest and extravaganza for the entire family to attend, to listen to the crimes of the accused, and to collect pamphlets regarding the crimes that had been committed. In the late 1800s and early 1900s, the rise of the so-called yellow journalists led to an increased number of sensationalist stories related to crime appearing in newspapers. These stories, in turn, drove up the number of sales and sometimes resulted in the printing of extra editions devoted to more coverage of what appeared to be a growing problem with crime.

As times changed, so did the mediums through which crime-related media were consumed. The newspaper continued to reign as the king of the media for many, but television began to supplant movie theater newsreels as the primary source for audiovisual media as the century continued. By the 1970s, most Americans owned a television set and had access to cable, allowing a wide-ranging variety of programming to watch. This period marked a turning point for the relationship of crime and the media, with 1972 witnessing the publication of Stanley Cohen’s important book *Folk Devils and Moral Panics* and George Gerbner and Larry Gross developing their cultivation theory in 1976. Between the two, the argument would be made that individuals would allow the media to help craft their social realities and their judgments about the nature and frequency of crimes that were occurring in the world around them.

In the 1980s, the first reality television shows relating to crime made an appearance, the most famous of which was *COPS*. Touted as being filmed on the streets with actual members of various police departments, the program failed to

demonstrate the often unremarkable nature of patrol activities, in favor of exciting chase sequences and a sense that crime had become an epidemic that was being fought continually each day without a pause for rest or respite.

During the period of the 1980s and 1990s, the landscape of media, especially television, became more amenable to the idea of trying to prevent crime from occurring. This led to several well-known campaigns, mostly focusing on the War on Drugs, such as the U.S. government’s “Just Say No” campaign. Popular television programs would engage in what was colloquially known as a *very special episode* in order to promote messages about not only drugs but also crimes against youth involving gang violence, hate crimes, and predatory sexual offenses.

It was during the 1990s that home Internet capability first entered into the public sphere and with it a new range of issues to address. For the first time, people could reach around the world to commit a crime against another average citizen in the course of minutes instead of taking days to travel and carry out an offense. The arrival of the Internet and its subsequent growth in the early 2000s has led to an explosive growth in the fields of cybercrime, cyberbullying, and cyberexploitation.

Media Representations of Crime in the 2000s

Given the lengthy history of the link between media and crime acting in an almost symbiotic nature with one another, it is not surprising that crime itself often is as an object of fictional representation in the media. In this way, the media acts almost as a surrogate for real-world experience that most individuals will fail to have, allowing for a worldview to form that is bereft of primary sources but built upon judgments learned from secondary materials that have been viewed and read.

These representations of crime in the media have not stopped with the advent of the Internet Age in the 1990s and 2000s but rather have continued to proliferate and expand with the ability to display the commission of new crimes that coincide with the rise of new technology. Likewise, older crimes, such as child predation, have a

new outlet, as Internet chat and messaging programs allow potential predators to converse directly with children around the world without ever leaving the confines of their own living room. The digital media that became available had directly influenced, perhaps for the first time in a generation, how the direct act of an older crime could be carried out.

This would lead to police departments establishing specific units to target online predators. Similarly, it would lead to citizens taking matters into their own hands and forming groups like Perverted Justice, which sought to expose predators. Eventually, the news media would bring all of the elements together for both entertainment and law enforcement purposes in the television program *To Catch a Predator*, where the host of the show, volunteers from civilian antipredatory groups, and law enforcement would lure a child predator to a home with the intent of arresting the predator after overtures of an explicit sexual nature had been made.

Internet-Based Media and Crime

However, some individuals feel that the media, by embracing these types of programs, is laying the groundwork for potential criminals to be able to commit crimes they would not have known how to do before, or get away with. The potential online child predator, one could argue, now knows what to look for, due to media coverage of the crime, and this will influence the predator to go in a certain direction with such attempts. The potential cyberbully will now know new tricks to utilize to continue to harass his or her victims, courtesy of the news coverage and made-for-television movies that have proliferated.

Furthermore, other older crimes, such as drug trafficking and counterfeit goods, have also benefited from the introduction of Internet media. In the 1980s and 1990s, drug dealers often had to walk the streets in order to secure customer orders; however, the arrival of the Internet allowed repeat customers to ask for more of a substance via instant messaging or e-mails without leaving their home. Entire networks have grown in relation to this type of trade, including the website known as the Silk Road, which offered a wide

selection of illegal drugs and other criminal products for sale.

Online media has also led to a rise in the ease of procurement of counterfeit drugs, which often advertise at a lower rate or as being from another country. Individuals who are either seeking a legitimate better price for their prescriptions or a chance to obtain prescription drugs without a visit to a qualifying physician can easily order a product that claims to be the drug in question, with only the need for a credit card and no other supplemental information that a legal supplier would need to obtain.

Perhaps the most prolific crime to be influenced by the rise of online media is that of music and video piracy. Prior to the Internet, the process of copying a cassette tape or video tape to another was an unwieldy and often slow process. However, with the recent evolution of technology and media, it has become easy for individuals to share music and movie files on peer-to-peer networks and websites such as The Pirate Bay in an often successful effort to bypass more legitimate forms of acquisition. Once connected to these websites, individuals are able to upload, or seed, their own files and select files, which others can offer for download as well, transferring the information, violating the copyright, and essentially stealing the song, video, or other information without paying for the product.

MEGAN'S LAW

Megan's Law is the name for several state and federal community notification laws that require government authorities in the United States to provide the public with information about registered sex offenders. Megan's Laws are named after 7-year-old Megan Kanka who was raped and murdered in 1994 by a twice-convicted child molester who lived in her neighborhood in Hamilton Township, New Jersey.

Megan's parents believed that her death could have been prevented if had they known that a sex offender had lived nearby. They successfully lobbied for passage of a sex offender community notification law, which was enacted as "Megan's Law" in New Jersey in 1995. Other states have passed similar laws also named after Megan, and in 1996, a federal Megan's Law was enacted.

The goals of Megan's Laws are to provide the public with information about sex offenders and their whereabouts to protect society and children, deter sex offenders from reoffending, and provide law enforcement information to better manage sex offenders.

Federal Megan's Laws

The federal Megan's Law of 1996 amended the federal Jacob Wetterling Act of 1994, which

required each state to keep a registry of relevant information about convicted sex offenders and make the information available to the public. Numerous states adopted variations of Megan's Law, but there was no standard as to what information should be collected or how to disseminate it to the public. In 2006, the Adam Walsh Act replaced the Wetterling Act, expanding federal sex offender policies for all 50 states, the District of Columbia, the principal U.S. territories, and federally recognized Indian tribes. Title I of the Adam Walsh Act includes a focus on community notification and is named the Sex Offender Registration and Notification Act (SORNA). The Adam Walsh Act also established the federal Office of Sex Offender Sentencing, Apprehension, Registration, and Tracking to develop guidelines and oversee the implementation and standardization of registration and notification practices across jurisdictions.

In 2016, President Barack Obama signed an International Megan's Law that requires a special designation posted on the passport cover of all registered sex offenders.

Implementation

By the late 1990s, all states had begun providing information to the public about convicted sex offenders, but community notification practices among states vary considerably. State practices vary in terms of who is required to register and for how long, who is subject to community notification, and what type of information is released and how it is released to the public.

The one community notification approach that all states have in common is that each posts information about convicted sex offenders on publicly available Internet sites. These postings commonly include the individual's name, picture, sex crime history, and location of residence. Publicly available Internet registries are considered passive community notification because the public must seek out information posted on the registry. Active community notification methods include press releases, mailed or posted informational flyers, door-to-door contacts by law enforcement, and community meetings in which law enforcement and other local agencies notify citizens when a sex offender moves within a locale.

To encourage states to standardize their notification practices, the Sex Offender Sentencing, Apprehension, Registration, and Tracking office released guidelines in 2008 to certify states' compliance with SORNA and updated the guidelines in 2011. States that do not comply with the guidelines may lose a percentage of their federal criminal justice funding. As of June 2016, 17 states had substantially implemented SORNA guidelines. The remaining states have implemented at least some community notification practices. A minority of states has calculated that implementing all of the SORNA guidelines would cost more than the federal criminal justice funding that they would lose for not implementing SORNA and have decided to not fully implement the guidelines.

SORNA guidelines require states to disseminate registry information to several agencies, such as the National Sex Offender Registry maintained by the Federal Bureau of Investigation, other law enforcement agencies, and supervision agencies such as probation departments. As well, SORNA guidelines require states to notify schools and public housing agencies in the locale in which a sex offender resides or is employed, social service organizations responsible for protecting minors in the child welfare system, and volunteer organizations that work with minors.

SORNA guidelines also require states to implement a three-tier risk classification system, which is meant to help inform the public and professionals about the level of risk a sex offender poses to the community. Under this three-tier system, individuals are classified by type of sex crime conviction as opposed to an individual assessment of sexual reoffense risk. The tier system proscribes a mandatory period of registration during which an individual will be subject to state-sponsored community notification. Tier I individuals are required to register for a period of 15 years, but under certain circumstances may be reduced to 10 years. Tier II individuals are required to register for a period of 15 years, and Tier III individuals are required to register for life.

A criticism of the three-tier risk classification system is that because it is offense-based it does not take into account that the criminal offense for which an individual is eventually convicted may not accurately represent the sexual offense the

individual actually committed or the individual's risk of reoffending sexually. This is because sex offenders, as do other defendants in the criminal justice system, commonly enter plea bargains in which they agree to plead guilty to a lesser charge instead of a more serious charge that carries more penalties. Consequently, compared to use of empirically based individualized risk instrument approaches, the three-tier offense-based classification system is more likely to overestimate the reoffense risk of some offenders and underestimate the reoffense risk of other offenders.

In some states, the level of community notification is matched to the offender's SORNA risk classification or a locally developed risk classification system, which may or may not use an evidence-based risk assessment tool. In other states, the same notification approach is used with all offenders regardless of the risk classification or level.

Characteristics of Sexual Offenders

Megan's Laws have received wide support from legislators and the public in part due to the misperception that most sex offenders will sexually reoffend. Sex offenders are a heterogeneous group in terms of their risk to reoffend and offending patterns. Individuals who have committed sex offenses have one of the lowest rates of reoffending among all types of offenders, typically around 10% or less over 5 years. In terms of offending patterns, most child molesters offend against children to whom they are related or acquainted. Thus, their sexual offending behaviors often are already known within their extended families and locales. Those who sexually offend against strangers typically present a higher risk to the public. In any given year, the vast majority of new sex offense arrests are of individuals who had not been previously identified as sex offenders by the criminal justice system.

Mental health professionals and child advocates note that juveniles who have committed sexual offenses are very different from their adult counterparts. These professionals have levied criticism of the sections of SORNA guidelines that include registration and notification requirements for juveniles as young as age 14 years, some of which can last a lifetime. Juveniles who have committed sexual offenses typically do not have

entrenched sexual offending behaviors, often respond well to treatment, or simply mature and do not continue offending. Juveniles typically have fewer numbers of victims and engage in less aggressive behaviors than adults who commit sex crimes.

Impact of Megan's Laws

Researchers have examined the impact of Megan's Laws on reducing sexual reoffending, as well as how professionals, the public, and sex offenders and their family members perceive and value community notification.

Community Safety

Overall, studies have found little evidence of reduced sexual reoffending as a result of Megan's Laws. This is a difficult area to study because there is considerable variation among and within states in how Megan's Laws have been implemented, the accuracy of information about offenders contained in publically available registries, and which offenders are subject to what types of community notification. The few studies in which Megan's Laws appear to have had an impact on reducing sexual reoffending are those that have been implemented in states (i.e., MN, WA) that have used evidence-based risk assessment instruments and focused community notification efforts only on higher risk offenders.

Public safety and wise use of public resources can be enhanced when community notification efforts focus on higher risk offenders. In addition, the public should keep in mind that only a small proportion of individuals who commit sex offenses have been detected and identified on public registries or by other means. Community safety efforts must focus more broadly than on the small proportion of sex offenders publicly identified through Megan's Laws.

Perspectives of the Public

Surveys of the public typically find strong support for Megan's Laws. Well above half of public members surveyed support community notification for all sex offenders regardless of their risk to reoffend, say they feel safer knowing about sex

offenders living in their communities, and believe community notification is effective in reducing sexual offending. Despite public support for Megan's Laws, only a minority of community members says they search out publically available information about sex offenders in their communities.

Perspectives of Professionals

Law enforcement professionals commonly report that sex offender registration and Megan's Laws are useful investigation tools. They typically report that Megan's Laws raise awareness within the community, improve community surveillance of sex offenders, and deter some sex offenders from reoffending. A concern of law enforcement is that implementing community notification activities can involve substantial labor and capital costs. Another concern of law enforcement is that some members of the public overreact to notifications that a sex offender lives nearby, to include harassment of offenders.

Probation and parole officers have reported that Megan's Laws sometimes make it challenging to help sex offenders obtain appropriate housing and employment because publically identified sex offenders are often ostracized in their communities.

Mental health professionals commonly express skepticism about the benefits of community notification. In surveys, most mental health professionals typically report that Megan's Laws either have no impact on community safety or may actually reduce it. Many mental health providers believe that community notification gives the public a false sense of security.

Perspectives of Sex Offenders and Their Family Members

Sex offenders and their family members have reported several unintended negative consequences of Megan's Laws. There are notable accounts of vigilante attacks against sex offenders who have been publicly identified on Internet registries and by other means associated with Megan's Laws. These attacks include murders and arsons, but these types of incidents appear to be quite rare. However, some sex offenders have attributed job

loss and difficulty securing housing as a result of being publicly identified a sex offender in their communities. In surveys, many sex offenders report that the stigma attached to community notification has resulted in psychological impacts such as stress, shame, hopelessness, and loss of social supports. On the other hand, some sex offenders report being more motivated to control their behavior knowing that others were monitoring them.

Megan's Laws also appear to have the unintended negative consequences on the family members of sex offenders. When sex offenders experience job loss and have trouble finding housing, this can result in financial hardship and social instability for their family members as well. In addition, some family members have reported being harassed as a result of their relationship with the offender, and in rare instances, they are the victims of assault. Family of registered sex offenders, including their children, have reported psychological consequences that they attributed to notification, such as experiencing anger, depression, and social isolation.

MENS REA

Mens rea generally means a guilty mind but in modern criminal contexts refers to criminal intent. Modern mens rea stems from English common law, which at that time meant evil intent, and has been established as a necessary element of crime in the United States. Mens rea is one of five elements that establish a crime, each of which must be present for an action to be considered criminal. These elements are actus reus (i.e., guilty act that was committed consciously and voluntarily), mens rea (i.e., criminal intent), the concurrence of actus reus and mens rea, causation, and a resulting injury or crime. To better understand mens rea today, it is important to know when and why it was first established as an element of crime; thus, this entry focuses on the development and evolution of the concept of mens rea as an element of crime.

Mens Rea in English Common Law

Intent has long been discussed as a part of criminal actions. However, it was not until the 17th century that English common law formally established the idea of mens rea being a necessary part of determining culpability. English common law produces many different, and often ambiguous, measures of an individual's intent to commit a crime. The common law was established out of a necessity for common rules and in its earliest stages was more a function of regulating compensation for a crime. There were three major legal influences on the creation of English common law: Anglo-Saxon law, church or canon law, and

Roman law. The foundation of English common law primarily came from Anglo-Saxon laws, which initially rejected Roman and canon laws, though they were later integrated into common law.

There were early Anglo-Saxon laws that included intent and in fact some crimes were considered impossible without it. Some crimes under these laws were rape, waylaying and robbery, and to some extent housebreaking. Other laws established the punishments based on the person's intent. These punishments could range from a felony, if the person intended the crime, to civil negligence, if the action was an accident. One example of this is arson: If the person's intent was to burn a house or barn down, then it was considered a felony; otherwise, it was considered negligence. Although some Anglo-Saxon laws acknowledged the importance of intent, others rejected it mostly in regard to the death of an individual.

Early Anglo-Saxon law regarding the death of an individual neglected to include intent as a part of establishing guilt and instead held people liable just for the act itself. These laws held people liable even in circumstances where there could be no knowledge that a crime would even be committed. The killing of an individual was only excused if the offender had a warrant from the king or was doing so in the pursuit of justice. An example of this strict liability would be if someone sent a messenger to deliver a letter and that messenger was killed along the way, the sender could be held liable for the death and owe payment to the next of kin. The common law that applies in this situation removes the legally liable person's mind-set altogether by holding the individual responsible for the actions of another, even though they had no way of knowing such actions would occur. Many of these laws, however, were thought to be made in a generally broad sense and were seldom used to actually hold individuals liable for such an incident. The way in which the Anglo-Saxon law was followed meant that a person could be held liable for the death of anyone acting under the person's direction or on the person's behalf. In addition, these laws excluded killing someone in self-defense, though the pardoning system was later established to correct this.

Around the 12th century, canon laws began to influence the Anglo-Saxon laws regarding death. Canon law placed much importance on intent

being a key element of guilt. A criminal act committed with intent made the offender morally guilty as well as legally guilty. The earliest reference to *mens rea* in an English law book came from teachings of the church. Canon law sought to determine sin through the examination of both the mental and physical elements of the crime. This conflicting idea made it difficult for common law judges to make rulings on liability in accordance with the Anglo-Saxon laws regarding death. The answer to this problem came from the king's ability to pardon individuals who had been charged with a crime. This allowed judges to follow the Anglo-Saxon law by finding a person guilty no matter his or her knowledge of the crime while still acknowledging canon law's insistence on intent being a factor. An unfortunate side effect to this solution was that individuals who would be pardoned still lost their possessions for being convicted. Canon law's influence on common law continued to strengthen regarding moral blameworthiness. Eventually, the phrase *actus non facit reum nisi mens sit rea*, meaning "there can be no crime, large or small, without an evil mind," became an essential part of criminal guilt.

The Roman law influence came around the 11th and 12th centuries, when universities began publishing scholarly and legal writings regarding old Roman law texts. The major influence of Roman law regarding intent came from the concepts of *dolus* and *culpa*. *Dolus* refers to intentional acts of fraud while *culpa* refers to negligent actions. These concepts reflect two different levels of intent and were therefore treated differently in regard to a criminal conviction. Beyond this idea of different levels of intent, Roman law also provided a number of standard definitions regarding crimes that helped establish true intent. Although Roman law continued to be referenced throughout the establishment of common law *mens rea*, it served as more of a tool to refine the term. This refinement helped strengthen the idea of *mens rea* until its acceptance in the 17th century.

After its universal establishment in common law in the 17th century, *mens rea* began to develop into a more precise definition to be used in criminal cases. *Mens rea* was initially a vague aspect of criminality and was purely based on general moral blameworthiness. The concept's refinement came

in the form of a case-by-case sharpening of the guidelines. Through the judicial process, cases in which different levels of mens rea existed were slowly placed into similar groups. This had to be done for each type of crime and resulted in a more precise interpretation of different mind-sets. Although this affected many types of crime, none changed more so than homicide. These changes allowed for additional justification for killing another person beyond a warrant and a pursuit of justice. Different types of murder began to develop with regard to the mental element of the crime. Any homicide that was not justifiable or pardonable was considered a felonious killing. Before these new laws, homicide had required the least amount of mens rea.

Mens Rea in Modern Criminal Law

As mens rea was sculpted from its origins as evil intent, it developed into these concepts used in today's criminal law. Using the American Law Institute's Model Penal Code, which was developed in the 1960s and updated in the 1980s, there are now established and widely accepted levels of mens rea that form continuity when determining culpability. The different levels of mens rea set forth by the Model Penal Code are specific intent, general intent, strict liability, and vicarious liability. Each of these is associated with a different state of mind, or level of knowledge, regarding a criminal act and, therefore, constitutes a different amount of legal culpability. Applying mens rea to a crime is the traditional way of determining capability. Intent means that the individual committing the criminal act did so with some level of knowledge or awareness that the act was illegal. Liability refers to an individual being held accountable for a criminal action regardless of mind-set. Liability is applied to lower level offenses like misdemeanors.

Specific intent covers actions committed purposefully and is the most culpable level of mens rea established by the Model Penal Code. Specific intent refers to a mind-set of specifically intending to commit the criminal action and specifically intending the results. This is the highest level of intent and therefore has the highest level of culpability. There are four types of crimes that fall under this category: SACs crimes (solicitation,

attempt, and conspiracy), theft crimes, intent to kill, and voluntary manslaughter or heat of passion killings.

General intent occurs when specific intent is not necessary because it is inferred by the individual's conduct. This intent can be classified as being purposefully (intentionally), knowingly (awareness of certainty), reckless (disregard for risks), or criminally negligent. Purposefully refers to when an individual intentionally acts with conscious objective to engage in a certain conduct or cause a certain result. Knowingly is when an individual acts with knowledge or awareness that the results are practically certain. Reckless refers to a situation in which the individual knows that there is an unjustifiable and substantial risk of harm. Criminal negligence is the lowest culpable classification of general intent and refers to an individual performing an action that greatly deviates from his or her duty of care that an ordinary prudent person would not do. This is also known as a gross deviation from tort standard of care. Examples of general intent crimes include rape, battery, arson, mayhem, involuntary manslaughter, and depraved heart murder.

Liability is separate from intent and refers to being held responsible regardless of one's intentions. Strict liability refers to actions where the individual's mind-set has no effect on guilt, meaning an individual is guilty just for committing the act. Actions that are covered by strict liability are often health, public welfare, and safety regulations such as speeding. Vicarious liability regards those who are responsible for another person's actions. Only in special circumstances is an individual held liable if he or she did not perform the action or even had awareness that a criminal act took place. An example of this would be a bar owner being held responsible for his or her employee selling alcohol to an underage individual. Courts are not legally required to use the Model Penal Code guidelines, though many have adopted them.

MENTAL DISORDERS AND VIOLENCE

Mental disorder refers to a variety of illnesses that influence mood, thinking, and behavior. A *symptom* of a mental disorder represents a specific functional disturbance (e.g., hearing voices in the absence of external stimuli, a psychotic symptom). A *syndrome* comprises a cluster of symptoms that tend to co-occur (e.g., lack of insight, disturbances in perception, and disorganized thoughts and speech are some of the individual symptoms that form the syndrome of psychosis). A *disorder* is a specific syndrome with a specific temporal course (e.g., at least two of five specific symptoms need to be present for 1 month to diagnose schizophrenia according to one diagnostic system). Although many people experience mental health problems at some point during the course of their life, such problems are only recognized as a mental disorder when signs and symptoms cause significant distress, dysfunction, or disability; are culturally abnormal; and impair functioning in one or more basic life domains, such as physical health, cognition or intellectual capacity, behavioral control, work or school performance, and interpersonal relationships.

Interpersonal violence—that is, actual, attempted, or threatened violence toward another person—is among the leading causes of death and injury in the United States and abroad. Numerous variables increase risk of perpetrating violence, such as a history of experiencing problems with relationships, employment, living situation, alcohol and drug use, complying with intervention and supervision, maladaptive personality traits, and procriminal or violent thoughts and attitudes. As will be reviewed in detail in this entry, serious mental disorder (SMD) also increases risk of perpetrating violence. However, the strength of the association on average is small to moderate in

magnitude, and people with SMD are more likely to be victims than perpetrators of violence. However, for some people with SMD, those symptoms may be strongly associated with risk of violence in one or more ways. The focus of this entry is on the types of SMD that on average have the largest associations with violence: psychotic and mood disorders.

Interpreting Discrepancies in the Research Literature

Decades of research on whether SMD is a risk factor for violence have yielded highly disparate findings. This large body of literature is marked by vastly different methodological and analytic approaches. Researchers have used different definitions of both SMD and violence, examined the topic using diverse types of samples across a range of settings, completed statistical analyses in some cases accounting for specific variables as confounding factors but not in other cases, and used varying degrees of methodological rigor, such as inclusion (or not) of a control or comparison group. Such dissimilarities have contributed to the conflicting conclusions reached by well-respected scholars about whether SMD is a risk factor for violence.

Why Understanding the Link Between Mental Disorder and Violence Matters

Acts of violence headline news daily. When an alleged perpetrator is suspected of having mental health problems, media portrayals often focus on the negative characteristics associated with the mental disorder. Sensationalized accounts can elicit fear among the public, perpetuate stigma and bias, and strengthen misconceptions that mental disorder is inevitably and strongly linked to violence. In fact, the same factors that increase risk of violence among individuals without SMD also increase risk among those with SMD. Nevertheless, that a link with SMD does exist for some people in some cases should not be ignored, both for the health and safety of the potential perpetrator as well as the victims. In addition, unlike any other risk factor for violence, mental disorder is afforded a special role legally. It is one of the foundations of involuntary civil commitment to hospitals in the United States and many other countries.

Also, individuals who commit violence as a result of major mental disorder may be found to be not criminally responsible for their actions if the disorder so affected their thinking that they did not know their behavior was wrong, or they were unable to make their behavior conform to the requirements of the law. Individuals found to meet the legal test of *insanity* in their jurisdiction may be sent to hospital for treatment but would not be sentenced to time in jail or prison.

Research on the Association Between Mental Disorder and Violence

Hundreds of studies have reported on rates of violence among psychiatric inpatients or rates of mental disorder among people with histories of known violence. By definition, such samples include relatively more seriously ill or violent individuals, and therefore investigations of this sort are prone to selection biases that make it difficult or impossible to apply their findings more generally. Although such studies are useful in many respects, larger scale studies that are less likely to be compromised by potential selection biases, such as epidemiological studies and meta-analyses, are therefore critical to consider.

Five key findings from such large-scale studies have been observed reliably. First, at the group level, there is a small to moderate association between SMD and violence; that is, although other risk factors, such as active substance use, may elevate risk of violence on average to a relatively greater extent, SMD nevertheless does increase risk of violence. Second, the association is a complex one whose strength varies as a function of several variables related to SMD itself as well as to the context in which it is studied. The association between SMD and violence is stronger when studied at the symptom, rather than diagnosis, level. Moreover, certain specific symptom clusters particularly elevate risk of violence, such as positive psychotic symptoms, manic symptoms, symptoms involving perceived threat, and symptoms characterized by anger and other negative mood states. The association also is stronger when people with SMD are compared to people with no disorders at all or to people with disorders with weaker associations with violence, such as anxiety. Relative to externalizing disorders such as alcohol

or drug disorders, SMD appears to not *further* elevate risk of violence. Third, the association is much stronger among individuals who experience co-occurring SMD and drug or alcohol problems than for individuals with SMD only. Fourth, SMD is as an important risk factor for violence among women as it is among men.

Methodologically rigorous studies of data collected from birth cohort samples around the world (e.g., Australia, New Zealand, Scandinavian countries, and Israel) provide support that a meaningful association exists between SMD and violence. Comprehensive epidemiological research in many of these same countries as well as in the United States offers, in general, the same pattern of findings. Another source of support for the empirical foundation demonstrating SMD to be a risk factor for violence is provided by meta-analytic investigations. Meta-analysis is a statistical technique for combining findings from independent studies. It is a powerful method for identifying patterns of results across numerous studies that may be obscured when studies are considered on their own. Several meta-analyses have examined the association between SMD and violence; most such studies have focused on the role of psychosis. Like any research study, meta-analyses are limited by the sample the researchers examine. Comprehensive meta-analyses that include all known individual studies conducted in diverse settings and with heterogeneous populations consistently have found a reliable but modest association between psychosis and violence. For example, in one study that aggregated findings from 166 independent data sets, psychosis was significantly associated with an approximately 49–68% increase in the odds of violence relative to the odds of violence in the absence of psychosis, representing a small, but reliable, effect size. The strength of the association, however, was moderated by several methodological variables.

Ways in Which Mental Disorder Could Increase Risk of Violence

When assessing the role of SMD on an individual's propensity for violence, several distinct pathways should be considered. It is possible that SMD could be a cause, correlate, or consequence of violence. SMD could play a *causal* role in violence

perpetration by influencing a person's decision to engage in violence, acting as a motivator, disinhibitor, or destabilizer. As an example of how SMD could act as a *motivator* to engage in violence, an individual with psychosis could have irrational, paranoid thoughts that others are trying to hurt her and decide to commit violence to neutralize a perceived threat. Despite the public perception that SMD frequently has a direct, causal link to violence in this manner, only a small proportion of violence committed by people with SMD would occur for such reasons. SMD could act as a *disinhibitor* for an individual if his or her symptoms made him or her less likely to be influenced by intrinsic or extrinsic checks against violence. For example, severe depression could lead an individual to become so preoccupied with his or her own problems so as to become less concerned with or aware of the consequences or costs associated with violence. Finally, symptoms of SMD could act as a *destabilizer* if they interfered with an individual's ability to monitor and control decision-making (e.g., as does emotional dysregulation and many cognitive-related symptoms of psychosis and major mood disorders).

SMD also could be a *correlate* of violence, increasing risk through its associations with other factors that in turn are associated with violence either directly or indirectly. This is because by definition SMD impacts one or more domains of an individual's functioning, and so the role of SMD must be assessed in context in terms of how it affects other potentially risk-elevating factors. As one example, persons with SMD may be partially or fully dependent on others for financial, social, and/or emotional support. Dependency on others has been known to heighten conflict in relationships that escalate to violence.

Finally, a reverse association may exist such that for some individuals, SMD may be a *consequence* of violence. Although relatively rare, for some individuals with predispositions, the stress associated with engaging in violence could cause mental health decompensation or exacerbate symptoms of an SMD an individual already may be facing.

Clinical, Research, and Policy Implications

Every comprehensive violence risk assessment must consider mental disorder. Importantly, however, the

mere presence of SMD for an individual does not mean she or he inevitably will perpetrate violence—SMD, though present, may not be highly relevant for all people. Evaluators conducting violence risk assessments should determine *how* SMD might influence risk factors for that particular person and then make recommendations or take steps to manage that risk. Risk factors for violence unrelated to mental health problems should be actively considered and, when appropriate, targeted for intervention.

Several worthwhile research avenues remain to be explored on this topic. For example, there is a dearth of theory-based research investigations; further work on the specific features of SMD that are risk-enhancing (i.e., types of symptoms; phases of illness) is needed; and examining the association between features of SMD and aspects of violence other than the nature of the violent act, such as motivations, imminence, and goals, would be fruitful.

Finally, if agencies and systems that are legally responsible for protecting staff or public from violence want to implement policies that are supported by research evidence, such policies must include consideration of SMD in decision-making systems concerning risk at various processing stages (e.g., at entry into a system, within a system such as when considering changing security or classification levels, and upon release to the community). Research-informed policies should explicitly highlight the need to consider the potential risk-enhancing role that SMD might play, if only to rule it out for a given individual.

MENTAL HEALTH ASSESSMENT

Mental health assessment refers to the evaluation of various aspects of an individual's psychological or mental functioning. In criminal justice contexts,

mental health assessments may be required or requested for a variety of reasons, from guiding basic mental health treatment for accused or convicted individuals to answering specific legal questions such as those related to criminal responsibility. This entry introduces the topic of mental health assessment in general, provides an overview of types of mental health assessments offered in criminal justice settings, and introduces the concept of symptom validity and malingering assessment.

Mental Health

To understand the role of mental health assessments in criminal psychology, one must first have a basic understanding of mental health and mental health assessments more generally. *Mental health* is a term that is used broadly to refer to various aspects of an individual's intrapersonal and interpersonal functioning. Mental health problems may reflect a variety of difficulties related to the individual's thoughts, emotions, or behavior. Much like physical health problems, mental health problems vary widely. First, mental health problems vary on several dimensions pertaining to time, including the likely age of onset or the expected duration of the illness. For example, some mental health problems tend to begin in childhood, while others tend to begin later in life. Second, mental health problems differ with regard to the domains of human functioning that they affect and with regard to the manner in which they affect them. For instance, an individual with a psychotic disorder may demonstrate bizarre behavior in response to unusual perceptual experiences (e.g., hearing voices that are not present), while an individual with depression may experience decreased energy and motivation resulting in difficulties completing activities of daily living, and an individual with an antisocial personality disorder may engage in risky behavior that violates the rights of others (i.e., criminal activities). Third, mental health problems vary in how they are perceived by the individual (e.g., the presence or absence of insight or distress) and by others (e.g., the extent to which interpersonal interactions are impacted). It is also worth noting that there are significant individual differences in terms of the symptoms, course, and severity of impairment

experienced by each person with a given mental disorder.

Common Elements of Mental Health Assessment

Some common components of mental health assessments include clinical interviews, reviews of relevant historical and file information, psychometric measures, and interviews with individuals familiar with the evaluatee. Clinical interviews may cover various aspects of the evaluatee's past and present functioning, from the onset and course of the presenting complaint to developmental milestones and patterns of social interaction. Reviews of background information, including pertinent files, can corroborate information discussed in the clinical interview and provide additional information that the evaluatee may not have reported. Psychometric measures include psychological tests and symptom/behavioral checklists, and they represent a structured approach to gathering assessment data. Many of these measures are associated with normative data, which allow the evaluatee's responses to be compared to those of a relevant population. For instance, an inventory of depressive symptoms might compare the evaluatee's pattern of responses to that of the community at large or patients with major depressive disorders or both. Finally, collateral interviews conducted with persons familiar with the evaluatee, such as family members, friends, or other service providers, can also provide valuable information and additional perspectives on the evaluatee's mental health and behavior across different contexts. While any one assessment may not contain or require all of these elements, it is generally recommended that an assessor consider more than one source of information. Each of these techniques can provide valuable information, but combining them can increase the assessor's confidence in the conclusions that he or she draws about an individual's mental health and behavioral functioning.

Formal Diagnostic Systems for Mental Health Problems

Given the considerable breadth and diversity of mental health problems experienced by persons around the world, these problems have been

categorized in order to facilitate efforts to understand and manage them. The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* and the *International Classification of Diseases and Related Health Problems, 10th Revision* are two examples of diagnostic systems that are widely studied and employed by mental health service providers. Primarily, these diagnostic systems contain disorders that were identified by observing symptoms that tend to cluster together, as opposed to illnesses that may be differentiated on the basis of a theoretical or etiological understanding of their underlying causes. While the developers of the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* and other diagnostic systems tend to acknowledge that not all mental health problems fit neatly within existing categories, these systems allow for more reliable diagnosis and for more systematic and generalizable research studies.

A critical component of the formal diagnosis of mental disorders is the consideration of various biological, psychological, and social factors. While mental health service providers adhering to different theoretical orientations may disagree on the exact factors or mechanisms that underlie psychopathology (i.e., impaired mental health), it is widely accepted that obtaining a broad history from a patient is necessary to arrive at a meaningful diagnosis. Relevant factors include social development and functioning, physical health, substance and alcohol use, educational and employment functioning, criminal history, and mental health history.

The need for such broad information may be best illustrated by an example. When meeting with an individual presenting with decreased energy, impaired appetite, and difficulty sleeping, a service provider might assume that the individual is suffering from a major depressive disorder. However, these same symptoms could also be explained by any number of physical health concerns, substance use, or a normative reaction to a recent loss (e.g., job loss, death of a loved one, loss of freedom associated with incarceration). Following from the last point, another important component of effective diagnosis is the differentiation of clinically relevant impairments from normal variations in functioning. For example, while the average person could reasonably be expected to react with

fear or anxiety when faced with genuine danger, a person with an anxiety disorder might be paralyzed with fear in response to relatively innocuous objects or situations. When differentiating between normative and abnormal functioning and reactions, it is also important to consider individual differences, such as age, culture, and gender.

Types of Mental Health Assessment in the Criminal Justice System

Identifying Basic Needs and Treatment Planning

Research suggests that persons with mental health problems are overrepresented within criminal justice settings around the world. As a result, mental health treatment may be offered to facilitate criminal justice processes, such as participation in criminogenic interventions intended to reduce risk of criminal recidivism (i.e., the commission of new offenses following release from custody). Offenders in many jurisdictions are also considered to have rights to basic mental health care, just like nonoffenders. Thus, general mental health assessments may be offered to criminal justice populations in a manner similar to those offered to community populations, in order to identify treatment needs and select interventions.

Competencies and Criminal Justice Processes

In order for an individual to participate in criminal justice processes, from the early stages of an investigation (e.g., participating in questioning by police investigators), through trial proceedings, and on to the administration of punishments, he or she must be deemed competent or fit to proceed. That is, the individual must have the mental capacity to understand and participate in the criminal justice process in question. While the various criminal competencies described in the following subsections are related concepts, they also differ in some important ways, including the specific elements required for competence and the time period of interest.

Competence to Waive Miranda Rights

Accused individuals are considered to have certain rights when detained for the purposes of an investigation or interrogation, even before

charges are brought against them. For instance, U.S. citizens are legally protected against forced self-incrimination. Statements made in the absence of a competent waiver of certain rights may not be admissible in court proceedings. These rights, often referred to as *Miranda rights* as a result of relevant case law, include the right to remain silent, the right to consult with an attorney and to have the attorney present during questioning, and the right to have an attorney provided if the accused lacks the resources to obtain one. In order to be competent to waive his or her Miranda rights, the accused individual must be capable of knowingly, intelligently, and voluntarily doing so.

Mental health service providers may be called upon by the courts to assess whether these three requirements were met in cases involving the waiver of Miranda rights. Several authors have recommended that assessors conduct a comprehensive mental health assessment, including a clinical interview; psychometric testing of cognitive functioning, personality, and response style/bias; contacting collateral information sources (i.e., other persons with knowledge of the individual or case); and reviewing documentation of the interrogation or investigation. Assessment of competence to waive Miranda rights focuses on the accused's mental state at the time of the investigation in question; in contrast, the accused's mental state at the time of the trial or assessment is not the central issue.

Competence to Waive the Right to Counsel

As mentioned previously, an accused individual has the right to legal counsel. However, accused persons also have the right to represent themselves, commonly referred to as *proceeding pro se*. In the United States, this right to represent oneself is protected under law, even in cases in which doing so may not be considered by others to be in the best interests of the defendant. However, similar to a waiver of Miranda rights, a waiver of the right to counsel must be made knowingly and intelligently. Importantly, competence to waive the right to counsel (i.e., understanding the possible risks and consequences of such a decision) may be distinguished from the competence or skill to actually conduct a strong defense.

Competence or Fitness to Stand Trial

Once charges have been laid and the accused proceeds to a criminal trial, the issue becomes one of competence or fitness to stand trial. Early legal documents pertaining to fitness for trial can be found among records of English common law dating to the 17th century. Under English law at the time, in order for accused individuals to undergo trials, they needed to possess a basic understanding of the pleas available to them, the possible outcomes of trials (e.g., the punishments they may face), and the types of information that might be appropriate for the construction of a legal defense. Under Canadian law, fitness to stand trial developed from an arguably ambiguous legal concept based on case law into a more clearly defined construct in the early 1990s and is now defined in the Criminal Code of Canada. To be found unfit to stand trial as a result of a mental disorder under Canadian law, accused individuals must be deemed unable to understand the nature or object of the proceedings, to understand the possible outcomes of the proceedings, or to communicate with their legal counsel. While the specific criteria vary somewhat by country or jurisdiction, the standards are similar in other nations, such as the United States and the United Kingdom.

It is important to note that assessors called upon to evaluate fitness to stand trial must consider the individual's mental state at the time of the trial; the individual's mental state at the time of the alleged offenses is irrelevant. Should the accused individual be found unfit to stand trial, the judge may halt the proceedings until such time as fitness may be restored. Thus, fitness or competence to stand trial is potentially dynamic; an accused individual who has been deemed unfit at one point during a trial may become fit through mental health treatment, training or education, or through the passage of time, at which point his or her trial may recommence.

Competence to Be Sentenced

Competence to be sentenced pertains to the accused's mental state in the period of time after a guilty verdict has been reached, but before a sentence has been rendered. This form of criminal competence involves the accused individual's ability to comprehend the sentencing process as well

as the possible sentences. Consistent with the broader concept of fitness to stand trial, competence to be sentenced can also be dynamic in nature. If the individual is deemed to lack this competence, the sentencing process may be delayed until such time as competence can be restored.

Competence to Be Executed

In the United States, some mental health service providers have been called upon to assess competence to be executed (i.e., to receive capital punishment). This concept has proven to be a legally and ethically complex one. An assessor could be asked, for example, to consider whether the offender understands that he or she has committed a crime, that he or she is facing execution, and that the execution is a result of the crime. While this may appear to be a relatively straightforward extension of the principles associated with other criminal competencies, it is problematic for mental health professionals who have professional and ethical commitments to refrain from doing harm to their patients or clients.

In February 2007, the American Psychological Association, the American Psychiatric Association, and the National Alliance on Mental Illness submitted an amicus brief to the U.S. Supreme Court regarding the competence to be executed. While the brief made reference to a specific case, more generally the parties argued that executing a prisoner who does not appreciate the nature of the penalty is inconsistent with the purpose of the death penalty (i.e., retribution for a specific crime). The Supreme Court agreed with the parties submitting the brief in this case and also noted that mental health professionals serving as expert witnesses could assist the court by conducting assessments of offenders' competence or mental state.

Mental Disorders and Criminal Responsibility

The idea that mental disorders may diminish legal culpability dates back at least 2,000 years, when the Roman leader Marcus Aurelius argued against conventional criminal punishments for insane offenders. While accepting that serious mental disorders may mitigate criminal responsibility could seem to be a straightforward concept to some readers, the practical implications of this

idea have long been a source of legal and political debate. As a result, the manner in which laws involving criminal responsibility and mental disorders are applied has changed over time and varies across nations and jurisdictions. For instance, in England in the 1700s, it was argued that an accused offender should not be held criminally responsible for an offense committed while lacking the understanding of a 14-year-old or if his or her understanding of the behavior was comparable to that of a nonhuman animal. Then, in the mid-1800s, a landmark case involving a man named Daniel M’Naghten resulted in further clarification of the standard for criminal responsibility in Britain. M’Naghten shot and killed a secretary to the British prime minister, having mistaken him for the prime minister himself, while under the delusional belief that the prime minister and his party were persecuting him. The courts acquitted M’Naghten on the basis of insanity and formulated what has come to be known as the *M’Naghten test* or *standard*. The standard can be summarized as follows: When an accused individual is not criminally responsible for an act committed while experiencing a disease of the mind that renders him or her unable to comprehend the nature and quality of the act or that it is wrong.

While the M’Naghten standard remains the basis of pertinent law in some nations and jurisdictions, including Canada and England, various courts have considered other standards. For instance, an alternative referred to as the *Durham standard* was used by federal courts in the United States in the middle of the 20th century and remains in use in New Hampshire. The broader Durham standard was developed in response to perceived limitations (e.g., restrictiveness) of the M’Naghten standard and essentially allows for an accused individual to be found not criminally responsible for any action that was the result of the mental disorder or defect. Another standard, developed by the American Law Institute in 1972, posits that a defendant should not be held criminally responsible for an act committed while experiencing a mental disorder that rendered him or her unable to appreciate the criminality of the act or to conform his or her behavior to the law. In 1984, the U.S. Congress passed new federal legislation pertaining to criminal responsibility, which requires the defendant to prove that at the time of

the offense, he or she was experiencing a mental disorder that rendered him or her unable to appreciate the nature and quality or wrongfulness of the behavior.

Mental Health Assessment of Criminal Responsibility

While the exact legal standards for criminal responsibility may vary, mental health assessments in this domain share some common elements. For instance, unlike fitness to stand trial assessments, which focus on the accused individual’s current mental state, assessments of criminal responsibility focus on mental state at the time of the offense. As a result, an assessment would generally involve a clinical interview with the individual in question, a detailed review of relevant documentation, and discussions with collateral contacts. Of particular interest to assessors are documents or individuals who may be able to provide insight into the accused individual’s thoughts, emotions, and behaviors as recalled or recorded before, during, and after the index offense (i.e., the offense that prompted the assessment). Examples include police reports summarizing the factual details of the offense, transcripts of any interviews conducted with the accused individual or other witnesses, and information gathered from persons with an intimate knowledge of the accused (e.g., family members, roommates, friends).

That being said, historical information, including records of previous involvement with mental health service providers, is also relevant to the assessment of the presence or absence of a mental disorder. This type of background information is necessary to assist the assessor in making a reliable determination of the presence or absence of a genuine mental disorder. Ultimately, both types of information are important, given that the assessor is responsible for evaluating both whether a mental disorder was present at the time of the index offense and whether that disorder impacted criminal responsibility, in keeping with the legal definitions outlined earlier.

Risk Assessment

Mental health service providers are often called upon to assess risk of violent, sexual, or general

offending behavior. Risk assessments may be requested at various stages of an individual's progression through the criminal justice system and may inform decisions about sentencing, supervision, placement or security level, and treatment or risk management activities. Many of the strongest and most reliable predictors of criminal behavior, including criminal history, are not specific to individuals with mental health concerns. Nonetheless, there is also evidence to suggest that mental health can be relevant to an assessment of risk.

Mental Illness as a Primary Predictor of Crime and Recidivism

Research on mental illness as a singular predictor of criminal behavior has produced conflicting results. On the one hand, some research has found only weak or no evidence for a relationship between mental health variables and criminal behavior. For instance, the influential MacArthur Risk Assessment Study, conducted in the 1990s, produced data on a sample of civil psychiatric patients in the United States. Some results from the MacArthur project indicated that diagnoses of schizophrenia were associated with a lower rate of violence over a 1-year follow-up period. In addition, reviews of the research on the best predictors of criminal behavior have identified eight risk factors, known as the *Central Eight*, as the most reliable predictors of general criminal recidivism, and these factors do not include diagnoses of a major mental illness.

On the other hand, there is also research to suggest that under certain circumstances, particular symptoms or diagnoses of a mental health problem are associated with criminal behavior and recidivism. First, diagnoses of some personality disorders can predict recidivism. More specifically, psychopathic personality disorder, antisocial personality disorder, and other personality disorders involving behavioral impulsivity and emotional instability, commonly referred to as *Cluster B personality disorders*, are associated with recidivism. In fact, antisocial personality pattern is counted among the Central Eight risk factors. Second, substance-related disorders, involving the abuse of illicit drugs or alcohol, are also associated with recidivism. In addition, when substance use disorders and some major mental illnesses co-occur,

what is known as a *dual diagnosis*, risk of recidivism is elevated. Third, research evidence indicates that deviant sexual preferences, including disorders of sexual preferences such as pedophilia (i.e., sexual attraction to children), are associated with sexually violent recidivism. Finally, meta-analytic research synthesizing data from multiple research studies has found a small but significant relationship between psychosis and violence; however, this research also found that the relationship between psychosis and violence varies widely depending on the setting, population, and symptoms being studied.

Mental Illness and Structured Risk Instruments

Research on risk assessment practices has demonstrated that structured risk instruments are the most robust known predictors of crime and recidivism. It is notable, then, that several of the most widely adopted and supported risk instruments contain an item pertaining to the mental illness domains described earlier. That being said, even in this body of research, the predictive relationships among mental illness and various forms of recidivism are complex. For instance, research on the prediction of violence among forensic psychiatric inpatients suggests that scales measuring acute mental health symptoms are strong predictors of institutional incidents over short-term follow-ups, while scales measuring more stable risk factors (e.g., criminal history) are stronger predictors of community recidivism over long-term follow-up periods.

Specialized Mental Health Assessment: Neuropsychological Assessments in Criminal Justice Settings

Unlike many other types of mental health assessment, neuropsychological assessments are intended to provide the evaluator with an understanding of underlying brain functioning. Neuropsychologists apply specialized knowledge of the anatomy and function of the central nervous system to the assessment and treatment of various neurological, medical, cognitive, and behavioral disorders. Neuropsychology has the potential to offer considerable insight into the behavior of individuals in correctional settings given that, for example,

incarcerated offenders tend to experience higher rates of head or brain injuries than the general population. Indeed, organic deficits that may contribute to impaired attention, memory, problem-solving, impulse control, or speed of responding are potentially relevant to decisions about sentencing, risk, offender management, and rehabilitation. However, service providers conducting neuropsychological assessments in criminal justice settings must be mindful of various ethical and practical complications. For instance, the interpretation of many neuropsychological tests relies heavily on normative data and patterns established from community populations, which tend to differ from correctional populations on a number of potentially relevant dimensions (e.g., education, intellectual ability, language, ethnicity). In addition, standardized administration procedures are essential to valid neuropsychological testing. These procedures include aspects of the assessor's dialogue with the client, elements of the physical environment (e.g., adequate lighting and freedom from distractions), and standards for the order and timing of particular tests. In criminal justice settings, each of these procedures may be difficult to follow.

Symptom Validity and Malingering

Mental health assessments in criminal justice contexts may address a variety of questions, and the techniques and methods employed by service providers can take many forms. However, while certain details may vary, mental health assessments share common elements, including the fact that they often require the collection of information directly from the subject of the assessment (i.e., direct questioning, behavioral observation, psychometric testing). Indeed, it is a reality of mental health assessments that many important questions relate to an individual's internal mental experiences, ranging from perceptual experiences, to general cognitive functioning, to comprehension of specific legal concepts. Mental health assessors must critically evaluate the validity of an evaluatee's self-report or behavior in any mental health assessment but must be particularly mindful of authenticity when the evaluatee may perceive an incentive based on the outcome of the assessment. For instance, certain evaluatees may wish to be

perceived as more or less impaired by their evaluators during assessments for criminal responsibility. While one individual might exaggerate or feign symptoms of a major mental disorder to avoid a period of incarceration in a prison, another individual might passionately deny the presence of a mental disorder while holding the delusional belief that he or she is the president of the United States.

For the purposes of this entry, symptom validity refers to the accuracy or genuineness of an evaluatee's self-report or performance or behavior during a mental health assessment. Malingering is defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* as the intentional production of false or exaggerated symptoms, and while malingering must be considered in many mental health assessments, it is not the only relevant concept related to symptom validity. Symptom validity may be called into question for a number of reasons, but it is worth noting that evaluatees may exaggerate, underreport, feign, or deny symptoms for a variety of reasons and that it is common for persons to intentionally and unintentionally influence how they are perceived by others. In addition, symptom validity is not an all-or-nothing concept; the fact that some elements of the evaluatee's presentation or self-report are of questionable validity does not discount all other elements.

Given that mental health assessments often focus on questions related to the evaluatee's internal mental state and given that symptom validity may be impacted by a variety of subtle or clear variations in behavior, the assessment of symptom validity is a difficult and important task. Nonetheless, mental health assessors do have a number of techniques available to them. For instance, some psychometric tests incorporate indicators of symptom validity within the tests themselves. There are also scales specifically designed to assess symptom validity and malingering. These psychometric indicators and scales may alert the assessor to concerns about response inconsistency, rare responses, response biases (i.e., excessively positive or negative responses), or malingered mental illnesses. In addition to specialized psychometric measures, assessors may compare clinical data to behavioral observations, collateral and historical information, and knowledge of relevant

research (e.g., common and uncommon symptom combinations).

Concluding Thoughts

Mental health assessments in criminal psychology may take many forms and address a number of questions. In addition to the principles of sound mental health assessments in general, service providers in criminal justice settings must also be mindful of additional factors, such as relevant legal concepts and questions about the validity of their evaluatee's self-report. These assessments are often complex and difficult but have the potential to offer various stakeholders unique and valuable information.

MENTAL HEALTH ASSESSMENT: ADULT SCREENING TOOLS

Mental health screening refers to the administration of a measure (typically self-report or interview) to offenders entering a criminal justice agency for the purposes of identifying those offenders who have a mental illness. Screening is necessary to ensure that appropriate interventions can be administered or referrals to community resources can be made. This topic is relevant to the field of criminal psychology because it reflects an intersection between clinical psychology (assessment of mental illness) and the criminal justice system (offender population). This entry focuses on mental health screening among adult offenders and describes (a) the purposes of mental health screening in various correctional settings, (b) characteristics of effective screening tools, (c) examples of promising screening tools, and (d) considerations for agencies administering these tools.

Purposes of Mental Health Screening

Screening is a first step toward identifying mental illness among offenders. There are a number of specific mental health screening tools, and these vary in the specific types of mental illness they are designed to detect. Some tools focus narrowly on the detection of serious mental illness (i.e., major depression, bipolar disorder, schizophrenia), whereas others seek to detect a broader range of mental illnesses such as post-traumatic stress disorder or personality disorders. Although some mental health screens detect suicide risk or substance abuse problems, not all do—separate screening tools exist for these conditions. Importantly, mental health screening tools do not yield psychiatric diagnoses; rather, they indicate which individuals are in need of further assessment by a mental health professional to determine whether a mental illness is present.

Screening has numerous purposes across different types of correctional agencies. In custodial facilities such as jails and prisons, inmates' mental illness are typically entitled to mental health treatment. Providing such treatment can additionally reduce the likelihood of disciplinary problems and custodial concerns. Furthermore, some jails operate in jurisdictions that have programs such as mental health courts or other types of diversion programs, and some prisons have units designated for inmates with mental health problems. Screening can be used to identify inmates for all of these purposes.

In community corrections (i.e., probation and parole), mental health treatment is often not provided directly by the corrections agency, but referrals may be made to treatment providers in the community when needed. Such treatment is an important component to effective community supervision because correctional interventions can more effectively address recidivism risk when symptoms of mental illness are effectively managed. Screening is a systematic way to identify offenders who need such treatment. In addition, some community corrections agencies have specialized caseloads for offenders with mental illness; screening is a mechanism to identify offenders who are eligible for these specialized placements.

Characteristics of High-Quality Screening Tools

There are both practical and psychometric features of mental health screening tools that should be evaluated when determining a tool's utility. Practical features include the format of administration and scoring procedures. Measures may be administered via paper and pencil, by interview, or by computer. Computerized measures are typically self-scoring, although these have been researched relatively less than the other formats. Paper-and-pencil forms may have simple scoring guidelines or may require professional judgment or specialized training to score. Interviews often require some degree of clinical training for staff to administer and score; as such, these may be appropriate only in settings where there is mental health staff. Paper-and-pencil tools may be more appropriate for community corrections settings, given that there may not be staff with mental health training,

and these measures' self-report nature is less demanding on staff time. In all correctional settings, the amount of time needed for an individual to be screened should be taken into account—screens with more items will take longer to administer.

Although there are many mental health screening tools available for use with the general population, screening tools used in correctional settings should be validated specifically for use in those settings to ensure that they adequately detect mental illness among criminal justice populations. This is important because the prevalence of mental illness is higher in correctional settings than in the general population, and there may be different response biases in correctional settings such as reluctance to report symptoms.

Effective screening tools should have strong psychometric properties, and ideally, there should be evidence of the tool's utility from multiple samples and facilities. In addition to standard psychometric properties such as test-retest reliability, research on screening measures typically reports statistics such as sensitivity and specificity. These statistics refer to the proportion of correct classifications made by a screening tool, generally in terms of the level of agreement between the screening tool and a diagnostic clinical interview. Screening tools generally have one or more cutoff scores to indicate which individuals *screen in* as needing further assessment, whereas clinical interviews assess for the presence of a psychiatric diagnosis. The sensitivity of a screening tool refers to the proportion of individuals who have a diagnosable mental illness who screen in on the tool or true positives. A screening tool with high sensitivity will correctly flag a higher proportion of offenders who have mental illness compared to a tool with low sensitivity. Specificity refers to the proportion of individuals who do not have a mental disorder who do not screen in on the screening tool or true negatives.

It is difficult to achieve both high sensitivity and high specificity in the same screening tool; typically, an increase in one comes at the expense of the other. Every screening tool generates some amount of incorrect classifications (i.e., an offender with mental illness classified as nondisordered on a tool, or vice versa), but tools differ in the extent to which they are likely to generate

false positives versus false negatives. Administrators making decisions regarding which tool to use must consider the relative consequences of different types of incorrect classifications when examining the psychometric properties of candidate tools. In agencies with extremely limited resources, there may be more emphasis placed on specificity, whereas agencies needing to ensure that all individuals in need of treatment receive it should look for measures with high sensitivity.

Because measures may perform differently with different subpopulations, psychometric properties of screening tools should be examined separately among inmates with various demographic characteristics. For example, women in correctional settings generally have higher rates of mental illness in general compared to men and have high rates of post-traumatic stress disorder in particular. Some screening tools have different versions for men and women or different scoring criteria by gender to account for this. In addition, there is evidence that some screening tools are less sensitive to mental illness among female offenders or offenders from certain ethnic minority groups. As such, administrators should consider evidence of a tool's utility in populations similar to their agency's.

Promising Mental Health Screening Tools for Adult Offenders

At least 20 mental health screening tools have been developed for use with adult offenders, but only a few of these have multiple studies reporting their psychometric properties. The vast majority of this research comes from institutional rather than community corrections settings. Next, some of the well-studied tools are briefly described.

Perhaps the most widely researched mental health screening tool for adult offenders is the Brief Jail Mental Health Screen (BJMHS). The BJMHS is based on the Referral Decision Scale and consists of 8 items that are answered in a yes-or-no format. Administration is done via interview and takes fewer than 5 min. The BJMHS has been examined in multiple studies across several U.S. jails, and this research indicates that it has relatively high sensitivity for serious mental illness (60–75%), although lower rates of accuracy were found for female offenders and ethnic minority

offenders. In addition, one study found that the original BJMHS had high sensitivity when used as a self-report form in a probation setting.

The Jail Screening Assessment Tool consists of a semi-structured interview and file review and involves the use of clinical judgment to score. The Jail Screening Assessment Tool is designed to detect a wide range of mental health and behavioral concerns, including mental illness, suicide risk, and violence risk. It has been examined among samples of male and female Canadian jail inmates, with sensitivity estimates ranging from 38% to 84% and specificity ranges from 67% to 71%, although estimates vary by setting and which disorders the measure is used to detect.

The Correctional Mental Health Screen (CMHS) has separate versions for men and women. The 12-item CMHS-M (male version) and the 8-item CMHS-F (female version) are composed of interview questions with a yes-or-no format; these items were derived from other mental health assessment tools that were found to be the most strongly related to mental illness in the tool's development study. The CMHS-M has demonstrated sensitivity of 70–74% for detecting any mental disorder, but higher sensitivity can be achieved by lowering the tool's cutoff score. Similarly, the CMHS-F has sensitivity around 65%, which can be increased with a lower cutoff score, although a higher rate of false positives are generated with lower cutoff scores. The CMHS development study examined the tools' utility with Caucasian and African American jail inmates and found that it had similar sensitivity with both ethnic groups.

Considerations for the Use of Mental Health Screening Tools

Despite the availability and utility of mental health screening tools, surveys of practices indicate that many jails use unstructured or unvalidated tools to screen for mental illness—the extent to which these tools identify offenders who have a mental disorder may be low or unknown. Research suggests that the majority of offenders with mental illness go undetected, so use of validated screening tools is important. This idea has caught the attention of governmental agencies such as the National Institute of Justice, which has issued recommendations for agencies calling for systematic

screening as part of a comprehensive mental health assessment and treatment procedure.

Agencies seeking to implement mental health screening should attend to guidelines such as those published by National Institute of Justice for best practices for use of these measures. For example, staff conducting screening should receive training on proper procedures for administration and scoring of the tool. If the screen is conducted via interview, training on rapport building with offenders is helpful. In addition, staff should be trained on proper interpretation of the results (including the fact that screening in on a tool does not necessarily indicate a diagnosis is present). Policies should be implemented to guide decisions based on screening results. As with any mental health assessment procedure, screening should be done in accordance with ethical guidelines, particularly in regard to privacy and confidentiality.

No screening tool is perfect—it is only a sample of information about an individual at a point in time. There are factors that can affect scores on screening measures. For example, the level of privacy where the screen is conducted and the ability of the professional conducting the screening can affect an offender's willingness to disclose symptoms or a history of treatment. In addition, administrators or staff may be concerned with malingering—inmates exaggerating or fabricating symptoms for the purposes of getting psychotropic medications or preferential placements. Although some inmates do try to feign symptoms of mental illness for secondary gain, staff must be cautious when responding to suspected malingering because the inmate may truly have a mental illness and thus would go untreated. Staff should also be made aware of the fact that some inmates, due to symptoms of mental illness or cognitive impairments, may have difficulty articulating the symptoms they are experiencing, which may be misinterpreted as malingering. On the other hand, inmates may be reluctant to disclose symptoms or hide their symptoms in an effort to avoid stigmatization by staff or other inmates.

In addition, different tools perform differently among different subgroups of offenders for a number of reasons. For example, members of ethnic groups may be less willing to disclose symptoms or experience mental health symptoms as physical problems; as such, staff should be trained

in issues related to cultural diversity. Moreover, staff screening female offenders should be trained in working with individuals who have a history of trauma, which is highly prevalent among women in the criminal justice system. Female offenders may be reluctant to share mental health concerns with male staff if they have a history of male abusers.

Research on mental health screening tools for adult offenders is ongoing. Some specific areas in need of attention include further refinement of measures to improve utility with women and ethnic minority offenders and development of translated tools for use with offenders with limited English proficiency. In addition, researchers have begun to use technology to improve screening, such as using computerized versions of diagnostic interviews or computerized scoring for screens that generates offender classification schemes. As research on these novel measures continues, agencies may be able to identify a higher proportion of offenders with mental illness.

MENTAL HEALTH ASSESSMENT: JUVENILE SCREENING TOOLS

Mental health screening refers to the administration of a brief measure to children and adolescents entering a juvenile justice agency for the purposes of identifying individuals who have a mental health problem or behavioral health concern. Screening ensures that mental health treatment or interventions to prevent self-harm are given to juvenile offenders who are in need of these services. This topic is relevant to the field of criminal psychology because it reflects an application of clinical psychology to the juvenile justice system. This entry focuses on mental health screening among juvenile offenders and describes (a) the purposes of mental health screening in juvenile justice settings, (b) characteristics of effective mental health screening tools, (c) examples of screening tools, and (d) considerations for juvenile justice agencies administering these tools.

Purposes of Mental Health Screening in Juvenile Justice Agencies

Since the mid-1990s, there has been an increasing amount of attention paid to the mental health needs of children and adolescents involved in the juvenile justice system. Policy makers such as the U.S. surgeon general note that many youth become involved in the juvenile justice system because of mental illness, and researchers note that youth with mental illness are disproportionately represented in the juvenile justice system. Although estimates vary depending on setting type and data collection method, most estimates suggest that about two thirds of juvenile offenders have some type of mental illness, such as depression, anxiety disorders, attention-deficit/hyperactivity disorder, substance abuse or behavioral disorders. This is at least twice as high as the prevalence rates found among youth in the community.

Agency administrators look to researchers for guidance on how to better meet the needs of the youth under their care. This may include diverting youth out of the justice system to treatment in the community or providing treatment within juvenile justice facilities to improve the likelihood that juvenile offenders can be rehabilitated and avoid further entanglement with the juvenile (or adult) justice system. In addition, juvenile offenders who are held in detention facilities are entitled to mental health treatment when needed. Upon intake to these facilities, it is important that youth are assessed to determine whether they are taking any medications that need to be continued or assessed, and whether the individual is at risk of self-harm so that suicide prevention procedures can be implemented. In addition, mental illness can be exacerbated in the stressful environment of detention centers, and youth with mental disorders may be at risk of behavioral problems that pose a risk to staff or other youths. As such, nationally recognized experts in juvenile mental health described structured mental health screening as a crucial step in addressing the mental health needs of juvenile offenders.

Characteristics of Effective Screening Tools

There are several characteristics that define effective mental health screening tools for use with juvenile offenders. Importantly, measures developed for use with adults are not developmentally appropriate for use with children or adolescents. Although inquiring about past use of mental health services can be a useful source of information, it cannot be the only source of information regarding a juvenile offender's current need for services, as many youth who need services do not receive them until they have contact with the juvenile justice system—this is particularly common among youth from ethnic minority groups.

Mental health screening tools in juvenile justice serve as a type of triage: distinguishing between youth who most likely do not have a problem needing immediate attention and youth who need immediate attention or further assessment. Screening tools should accomplish these goals in an economical and efficient manner and should assess for all types of mental health problems that

warrant attention in juvenile justice settings; these include major mental illness (e.g., depression, anxiety disorders, psychosis), substance abuse, and behavioral disorders such as oppositional defiant disorder and conduct disorder. In addition, the tools should identify suicide risk.

Mental health screening measures are available in a variety of formats, including paper and pencil, interview, and computerized administration. To ensure that the tool is administered properly, there should be structured administration guidelines such that similar results are obtained regardless of who administered the tool; these guidelines typically are described in an accompanying manual with clear training procedures provided to teach staff members to administer the tool. In addition, there should be clear scoring guidelines with cutoff scores to aid decision-making. For example, a scale assessing suicide risk should have a clear cutoff score to separate youth who are not likely at risk of self-harm from those who need intervention.

Screening tools should be researched extensively before being put to use in aiding decision-making for youth in the juvenile justice system. For example, cutoff scores to determine whether the individuals need further assessment or not should come from evidence across multiple samples of justice-involved youth; there should be evidence that the cutoff score accurately categorizes individuals from a wide range of ethnic backgrounds and both genders. In addition, there should be evidence of strong psychometric properties of the measure. There are many properties that should be evaluated; some of the more important ones to consider are test-retest reliability, interrater reliability, and construct validity. In addition, there should be evidence of clinical utility or the extent to which the measure aligns with the problems it is intended to detect. Information regarding clinical utility can be gleaned by assessing the measure's sensitivity and specificity; both of these reflect the measure's degree of correct classifications (true positive and true negative, respectively). A number of mental health screening tools are routinely used in juvenile justice settings; two of these (the Massachusetts Youth Screening Instrument-Version 2 [MAYSI-2] and the Child and Adolescent Functional Assessment Scale [CAFAS]) are reviewed in the next section, although many others are available, such as the

Problem Oriented Screening Measure for Teenagers and the Diagnostic Interview Schedule for Children (DISC) Predictive Scales.

Examples of Screening Tools

The MAYSI-2 is both the most well researched and widely used mental health screening tool developed for use in juvenile justice agencies. The MAYSI-2 was developed in samples in Massachusetts and California but has been tested in dozens of sites since its development. The MAYSI was designed to detect symptoms indicative of a wide range of mental health and substance abuse problems as well as suicide risk among youth between the ages of 12 and 17. It consists of 52 yes-no items and seven scales for boys and six for girls: Alcohol/Drug Use, Angry-Irritable, Depressed-Anxious, Somatic Complaints, Suicide Ideation, Traumatic Experiences, and Thought Disturbance (the Thought Disturbance Scale is not valid for girls). Administration of the MAYSI-2 takes approximately 15 min and can be done via paper and pencil or with the MAYSIWARE software. Scoring the MAYSI-2 is done by summing the number of yes responses for each scale, and each scale (except Traumatic Experiences, which does not have a cutoff score) generates a score of Normal, Caution (indicating the individual may have a clinically significant problem in that domain), or Warning (the individual is in the 10% of youths on that domain). Since its development, it has been translated into at least 12 languages, although less research exists regarding the utility of the translations compared to the original English version. Substantial research on the English version of the MAYSI-2 supports its correspondence with lengthier measures of psychopathology including clinical interviews. The MAYSI-2 has been widely adopted across facilities in the United States and other nations.

Another available screening measure is the CAFAS. The CAFAS was developed to detect problems or risk of problems in a number of domains, including behavioral, mental health, and substance abuse. It is appropriate for use with youth between the ages of 5 and 19 in the juvenile justice system as well as other contexts (e.g., schools). The CAFAS has 10 subscales that yield a total score. Eight subscales assess the youth's

functioning across important domains (School, Home, Community, Behavior Toward Others, Moods, Self-Harm, Substance Abuse, and Thinking); two subscales assess the caregiver's ability to meet the youth's needs (Material Needs and Social Support). The CAFAS is designed to detect need for further evaluation or services across the domains it assesses in addition to change over time during intervention. The CAFAS is scored by a trained rater; items primarily assess observable behaviors gathered from observation and reports from the youth and caregivers. Subscales yield scores indicating the level of impairment in that domain: minimal or no impairment, mild, moderate, or severe impairment. The CAFAS is available in both English and Spanish versions. There is substantial evidence of the CAFAS's ability to identify youth with serious problems in the juvenile justice system.

Implementation of Screening

For screening to be effective, every individual entering a juvenile justice agency should be screened at intake. In custodial settings, it is particularly important that screening occurs soon after entry (e.g., within a few hours) to quickly identify individuals at risk of suicide. It is important that screens are administered in a standardized manner, so staff who administer screening measures should receive appropriate training on administration of these tools. In addition, staff should be trained on how to maintain the privacy of youth both during the screening process and afterward when managing the data from these tools. It is recommended that agencies have clear policies on how staff should respond to youth who are identified by a screening measure as being in need of further attention.

When selecting a screening tool, implementing administration, and training staff, administrators should account for the specific needs of the specific population in their agency. This includes known differences in mental health needs for subgroups of juvenile offenders. For example, boys have higher rates of externalizing (behavioral) problems compared to girls, whereas girls have higher rates of internalizing (depression, anxiety) problems. Furthermore, girls have a higher prevalence of mental illness in general and

higher rates of co-occurring mental illness and substance abuse. There is some evidence that ethnic minority youth report lower rates of mental health concerns, but it is not clear the extent to which this is due to differences in prevalence or reporting of symptoms. Importantly, ethnic minority youth who are in need of services are disproportionately less likely to receive services compared to European American youth; as such, careful attention should be paid to the needs of ethnic minority youth during screening and service referral.

Although researchers note that mental health screening has not yet been implemented universally, there is strong consensus that mental health screening is an important first step toward identifying youth in the juvenile justice system with mental health, substance abuse, or emergent behavioral problems so appropriate interventions can be administered.

MENTAL HEALTH ASSESSMENT: SCREENING TOOLS

While screening can include a wide range of activities (e.g., laboratory tests, genetic screening), in the criminal justice system screening typically refers to a brief, but systematic process to aid in the detection of mental illness. Screening tools can often be administered by nonmental health professionals, including correctional officers. They may also be self-report questionnaires, which can be completed either by paper or on a computer. They are not intended to make a diagnosis, rather they aim to distinguish persons who likely have an illness from those who are unlikely to have an illness. Individuals who screen positive should be seen by a mental health professional for a full assessment to arrive at a diagnosis and treatment plan as appropriate.

People with mental illness are overrepresented in the criminal justice system. These inmates often have poorer outcomes including difficulties completing correctional programs, self-harm and suicide, institutional violence, and more time in segregation. Studies in various countries have reported that only 25% of inmates with mental illness receive treatment in jails and prisons. Screening is proposed as a solution to address this issue by supporting improved detection of mental illness. The end goal is to improve outcomes of offenders with mental illness. Several criteria have been proposed to evaluate how effective screening is at achieving this goal. The best

known criteria are a series of 10 criteria proposed by James Maxwell Glover Wilson and Gunnar Jungner for the World Health Organization in 1968. This entry reviews four criteria that influence the effectiveness of screening:

1. the accuracy of the screening tool
2. definitions of mental illness
3. the follow-up assessment and treatment services provided
4. the needs and treatability of those who are newly identified by screening.

Accuracy of Screening Tools

Whether a screening tool is accurate is typically determined by comparing the screening result to a gold standard assessment that is thought of as being the best measure of the person's true mental health status. This might include a structured diagnostic interview (e.g., the Structural Clinical Interview for DSM Disorders) or an in-depth clinical assessment. If a person is deemed highly likely to be ill on the screening test (i.e., a positive screen) and diagnosed as ill on the gold standard measure, the person is classified as a true positive. Conversely, a person is classified as a true negative if both the screen and the gold standard measure agree that the person is not ill. False positives (i.e., a positive screen for a person who is not ill according to the gold standard) and false negatives (i.e., a negative screen for a person who is ill according to the gold standard) thus represent screening errors.

There are a number of statistics that can be used to estimate the accuracy of a screening tool. Sensitivity and specificity are the two most common statistics used for this purpose. The sensitivity represents the percentage of people who have an illness who are identified by the screening tool as having a probable mental illness. That is why it is also referred to as the *true positive rate* of a screening tool. The specificity, or the *true negative rate* of the test, is the percentage of people who do not have an illness who are identified by the screening tool as unlikely to have a mental illness. When developing or implementing a test, one must decide the relative importance of true and false positives. On most tests, a cutoff score is

used to convert total scores into those who are classified as positive or negative screens. A lower cutoff score will increase sensitivity but decrease specificity and would be favored if missing cases of illness is the top priority, and the harms associated with false positives are low. A higher score can be used to increase specificity but decrease sensitivity. This would be favored if the harms associated with false positives are high (e.g., resource implications for follow-up services, high risk of side effects if treatment is provided to a person who is not ill).

Sensitivity and specificity are commonly reported because they are in most cases constant properties of a test that are not affected by prevalence (however, this property will not hold, if the screening accuracy of the test varies between groups of differing individual or clinical characteristics, such as disease severity; this is referred to as *spectrum bias*). To illustrate, Prison A is a maximum security prison, and Prison B is a minimum security prison. Because inmates with mental illness have higher rates of risk factors and behaviors, the prevalence of mental illness is 35% at Prison A and only 5% at Prison B. If all inmates are screened upon their transfer into the prisons, one would expect the same percentage of inmates with mental illness to be identified by screening in both cases. This is because how a person is rated or scored on a screening test should reflect the person's unobservable mental health status. If a person is ill, there is a certain likelihood that the

person will report those symptoms (i.e., the sensitivity of the test). Similarly, among those who are not ill, the specificity is the likelihood that they will not report symptoms.

While sensitivity and specificity are useful from a research perspective, they are less useful to a clinician reviewing screening results. This is because sensitivity and specificity start from the outcome and work backward to predict the screening result. Clinicians do not know the inmate's illness status (if they did, the assessment would not be needed) and therefore need to judge how accurate the screening result is. The positive and negative predictive value (NPV) of a test provide this information. The positive predictive value (PPV) indicates the percentage of people who are identified by screening as likely to have an illness (i.e., screen positive) who are in fact ill. The NPV indicates the percentage of people who are identified as unlikely to have an illness (i.e., screen negative) who are not ill. The limitation of PPV and NPV is that they are related to prevalence. The same test will have a higher PPV and a lower NPV in population with a higher prevalence (i.e., Prison A in the illustration) compared to a population with a lower prevalence (i.e., Prison B). If the prevalence is higher in the population, it must also be higher within the two groups defined by the screening result. Table 1 shows the calculations of these four statistics for Prisons A and B.

As seen in Table 1, the sensitivity (80%) and specificity (60%) of the test are the same in both

Table 1 The Accuracy of a Screening Tool in Settings With Different Prevalence

<i>Prison A</i>				<i>Prison B</i>			
	Not ill	Ill	Total		Not ill	Ill	Total
Screen negative	390	70	460	Screen negative	570	10	580
Screen positive	260	280	540	Screen positive	380	40	420
Total	650	350	1,000	Total	950	50	1,000
Sensitivity = $\frac{\text{ill and screen positive}}{\text{ill}} = \frac{280}{350} = 80\%$				Sensitivity = $\frac{40}{50} = 80\%$			
Specificity = $\frac{\text{not ill and screen negative}}{\text{not ill}} = \frac{390}{650} = 60\%$				Specificity = $\frac{570}{950} = 60\%$			
PPV = $\frac{\text{ill and screen positive}}{\text{screen positive}} = \frac{280}{540} = 52\%$				PPV = $\frac{40}{420} = 10\%$			
NPV = $\frac{\text{not ill and screen negative}}{\text{not ill}} = \frac{390}{650} = 85\%$				NPV = $\frac{570}{580} = 98\%$			

prisons. However, in Prison A, 52% of inmates referred by screening have an illness, whereas only 10% of inmates referred by screening in Prison B have an illness. In other words, in Prison B, inmates referred to clinicians for follow-up assessments are much more likely to not have an illness, whereas in Prison A, approximately half of the inmates referred following screening will have an illness. The situation in Prison A reflects the major challenge of trying to predict rare events. This issue has received considerable attention in screening for rare outcomes such as suicide and self-harm.

A 2013 systematic review found that the best studied mental health screening tools for use in jails and prisons have a sensitivity between 60% and 75% and specificity between 50% and 75%. At these levels of accuracy, screening would detect 2–3 times as many inmates with illness as compared to studies in settings without screening but with a relatively large number of inmates without illness also requiring assessments. Many screening tools are less accurate when used with women offenders. There was little research conducted with minority ethnic and cultural groups identified in the review. Gender- and culturally sensitive screening are important gaps in research and practice. Since accurate diagnosis is a precursor to treatment that can improve outcomes for inmates with mental illness, well-validated screening tools are an important component of a correctional mental health strategy. The following sections discuss some of the issues that must be attended to once an accurate screening tool is identified.

Diagnosis Definitions and Screening

There are a number of important issues surrounding the definition of mental illness that will affect decisions about when to screen and how effective screening is. These include the following: (a) the distinction between incident and prevalent illnesses, (b) whether there is a presymptomatic (or prodromal) phase during which early intervention can prevent onset or course of illness, and (c) overdiagnosis.

Incident Versus Prevalent Illness

The distinction between incidence and prevalence is critical to understand the risk that a person with mental illness poses. Incidence (or an incident illness in the individual case) refers to a new illness that has

its onset within the days or weeks prior to screening. Prevalence (or a prevalent illness) refers to a long-standing illness, which, in the case of discussing newly detected cases through screening, was previously undiagnosed. This question is important in terms of determining the timing at which screening should be offered. Most research on screening in jails and prisons focuses on the intake period. In the context of suicide risk screening and assessment, this is often recommended following transfers between institutions. If most illness in prisons predates incarceration (i.e., is prevalent), then intake screening is an appropriate strategy. If screening seeks to identify illness that has its onset during incarceration, then repeated screening at critical risk periods or at a regular interval is needed.

Prodromal or Presymptomatic Phase

In many health screening contexts (e.g., cancer), the goal is to identify abnormalities before they cause the individual to experience symptoms. This is less common in mental health screening, although some researchers have explored the preventive value of identifying prodromal symptoms (i.e., early signs that indicate a developing mental illness, prior to its actual occurrence), especially in schizophrenia and other psychotic disorders. Given that the age distribution of jail and prison populations overlaps with the typical time of onset of many mental illnesses, some have argued for screening for prodromal symptoms. This area is much less developed than other areas of screening, possibly owing to challenges in defining and measuring prodromal symptoms.

Overdiagnosis

Overdiagnosis refers to the situation in which an individual may be diagnosed with an illness that would not have been diagnosed in the absence of screening, but the diagnosis is not associated with impaired functioning or increased risk of adverse outcomes. In other words, the prevalence rate of the illness may be higher after introducing screening, but the newly identified cases are mild in severity. This should not arise in the context of diagnoses of mental illness made by a mental health professional given that most diagnostic criteria include a functional impairment criterion. However, critics of diagnostic classification systems (e.g., the

Diagnostic and Statistical Manual of Mental Disorders; *International Classification of Diseases*) argue that each revision has lowered the threshold for what constitutes an illness and thus increased overdiagnosis. Overdiagnosis has been raised in many other areas of medical screening (most notably cancer). Discussion of overdiagnosis in the context of mental health screening has only begun since about 2005 in the general population, and this issue has not been discussed in a criminal justice context where the emphasis has been largely on preventing missed cases of illness. If screening results in overdiagnosis, it may appear as though screening is ineffective as the prevalence of mental illness and potentially the rate of treatment use will increase. However, since the new service users are low risk, there may be no change in long-term outcomes. Overdiagnosis may also create a situation in which the highest needs cases do not receive the treatment needed due to a lack of resources to meet the demand created by screening. In this case, screening could lead to higher rates of adverse outcomes due to undertreatment.

Follow-Up Assessment and Treatment Services

As screening is not meant to determine an offender's diagnosis by itself, follow-up services by a mental health professional are required. Ensuring that there are sufficient resources to provide timely structured assessments for all those who are referred by the screening tool and treatment for all those who are identified by screening as likely to be ill is essential. These follow-up services represent an opportunity to identify mistakes that are made by screening tests (i.e., to rule out illness for inmates without illness who are incorrectly referred). However, if the PPV of a test is low, there is a greater risk that an individual with mental illness may be overlooked by the clinician. Conversely, if clinicians place too much emphasis on screening results and set out to confirm them, there is a risk of starting treatment for an inmate without mental illness, which may have important side effects or contribute to stigma.

Needs and Treatability of Newly Identified Cases

In most medical contexts, screening is offered only to those who are not known to have an

illness; in mental health research and practice, screening has often been offered to all individuals. Many mental health screening tools (e.g., the Brief Jail Mental Health Screen, Jail Screening Assessment Tool) include items about prior mental health service use, owing to fragmented service delivery among civil, forensic, and correctional mental health services. Despite their illness being known to a service provider, this information is often not available quickly enough to staff in jails and prisons to act on it. Most studies that have looked at detection of mental illness in prison have reported that detection is reasonably high for inmates who used mental health services in the community, and thus screening may have little or no impact on the outcomes of these inmates since they would likely be identified and treated even in the absence of screening. However, this finding is not consistent across countries, and given the importance of ensuring continuity of care, effective strategies for obtaining inmates' mental health histories (either through improved information sharing or self-report screening) are essential. As of the end of 2015, no research looking at the needs and treatability of inmates whose mental illness is first detected by screening had been conducted. Studies in primary care in the community have found no benefit of screening in terms of symptom reduction associated with screening, and that psychotherapy is less effective for individuals who are referred by screening compared to those who are referred by a physician or other health professional. Given that rates of detection of illness are lower in correctional settings than in the community, and inmates have many co-occurring health and social functioning needs, it is unclear whether these findings generalize to the jail and prison context. The question of long-term outcomes following screening represents an important clinical and research question moving forward, that has only recently begun to attract attention.

MENTAL HEALTH COURTS

Mental health courts (MHCs) are specialty courts designed to divert adults with mental illnesses from jail into behavioral health services. At any given time, the large and growing number of persons with mental illnesses in jails and prisons and under community supervision arrangements (i.e., probation and parole) presents significant challenges to mental health and criminal justice authorities. Persons with mental illnesses in the justice system have high rates of substance use disorders and chronic physical health problems and often have difficulty accessing health and behavioral health services, safe and adequate housing, and employment upon release from jail or prison. As a result, persons with mental illnesses have higher recidivism and probation revocation rates compared to justice-involved persons without mental illnesses.

A variety of interventions at the interface of the criminal justice and mental health systems have evolved to address the overrepresentation of persons with mental illnesses in the justice system. Crisis intervention training for police officers and MHCs is designed to divert persons with mental illnesses from jail to treatment; forensic assertive community treatment and forensic intensive case management are designed to prevent recidivism for justice-involved persons with mental illnesses; and specialty mental health probation is designed to ensure probationers with mental illnesses complete probation successfully without recidivism or revocation. This entry focuses on MHCs as one diversionary tool embraced by some local judicial systems to divert persons with mental illnesses to community-based treatment.

MHCs Defined

Since the first MHC in 1997, interest in the model has continued to grow. In 2000, U.S. president Bill Clinton allocated \$10 million toward the development and proliferation of MHCs through the America's Law Enforcement and Mental Health Project Act, which created the MHCs Program under the Bureau of Justice Assistance. Federal funding for MHCs continued throughout the 2000s and as interest in these courts has grown, so has their number.

In 2009, the United States registered more than 250 MHCs, and as of 2017, there were over 350 nationally. MHCs aim to reduce the frequency of contact between people with mental illnesses and the justice system by linking them to supportive resources, including community-based treatment, case management, employment, and housing. The rationale for developing MHCs in most communities is remarkably consistent and reflects a collective desire to increase public safety, improve quality of life among persons with mental illnesses, and maximize use of limited criminal justice and mental health resources. Typically, in exchange for successful completion of an MHC, a defendant's criminal charges are dismissed.

In general, MHCs share the following core components: (a) a docket exclusive to persons with mental illnesses, (b) voluntary participation as an alternative to the traditional court system, (c) a general goal of reducing jail time by directing participants to community-based resources, (d) a

team approach emphasizing cooperation through strong relationships between legal and behavioral health-care professionals, and (e) ongoing observation and monitoring by an MHC team to ensure participants adhere to explicit terms of participation. In addition, there are a number of process-oriented components shared by many MHCs, including obtaining stakeholder input, ongoing and meaningful use of collected outcomes data, mechanisms to ensure informed choice and confidentiality, and ongoing training for the MHC team.

MHCs also have distinct features that, to a large extent, are driven by local factors such as the availability of funding, the availability of services, and the willingness of a judge and treatment team to broaden MHC eligibility criteria to include more serious charges, such as violent felonies or sex offenses. Some MHCs have a single dedicated judge whereas others utilize a rotating panel of judges. Differences also exist in the use of sanctions and incentives, with some MHCs more likely to use jail as a sanction for noncompliance relative to others. Length of participation varies across MHCs, depending on the level of charge, degree of monitoring, and terms of participation. Finally, a number of MHCs started with federal seed money whereas others were developed with local or state funds.

Development, Theoretical Perspectives, and Criticisms

A number of factors stimulated the rapid dissemination of MHCs. These factors include deinstitutionalization, which moved greater numbers of adults with mental illnesses to community settings where adequate services and treatments were lacking and where there was continued deterioration of the social safety net for vulnerable populations. Other contributors include limited funding for mental health services at state and local levels and the existence of few criminal justice diversion programs for persons with mental illnesses in the 1990s.

Arguably, the perspective that untreated mental illness is a primary driver of low-level, nuisance crimes among persons with mental illnesses (i.e., the criminalization of mental illness) has motivated the development of MHCs across the United

States. The justice system has been described metaphorically as a revolving door for persons with mental illnesses in which jail serves to exacerbate symptoms of mental illness, thus contributing to a repeat cycle of offending. The prevailing sentiment is that if justice-involved persons with mental illnesses could be diverted into treatment, future criminal activities would desist. More recently, however, scholars point to criminogenic factors (i.e., antisocial attitudes, antisocial peers) as a primary cause of criminal activities, and there is evidence that these criminogenic factors are the same and equally, if not more, prevalent in justice-involved persons with mental illnesses relative to those without mental illness.

Finally, guided by the success of the drug court model, MHCs increased the visibility of justice-involved adults with mental illnesses and promoted the philosophy of therapeutic jurisprudence or *law as therapy*, which supports the assumption that law can be a social force used to foster behavioral change. In the context of MHCs, therapeutic jurisprudence incorporates current knowledge of best treatment practices and considers how they may be used therapeutically when applying the law to improve behavioral health outcomes. This concept has frequently been used to justify MHCs and is reflected in their design: MHCs incorporate voluntary participation and respect for autonomy, both of which are hoped to make MHCs more ethical and conducive to behavioral change.

Although MHCs have flourished in recent decades, they have not been immune to criticism. Whether defendants with mental illnesses can voluntarily agree to participate in an MHC is an ongoing criticism. Because MHCs, like other specialty courts, rely on the role of the judge to enforce behavioral change, MHCs may eliminate the role of the judge as a neutral figure and increase the coerciveness of participation. Threats to defendants' due process rights are another central criticism. Concerns about procedural justice center on whether defendants with mental illnesses are competent to engage in plea bargaining as part of the MHC process.

Furthermore, some critics argue that the adversarial system of justice is compromised when defense attorneys engage in a team-based approach to legal decision-making on behalf of their clients.

In addition, MHCs may exacerbate stigma toward persons with mental illnesses by creating visibly segregated and disparate legal processes. Finally, success of MHC is contingent on availability of community-based resources, and resultant demand on limited local infrastructure increases the potential for resources to be preferentially diverted to justice-involved persons with mental illnesses rather than those who are not justice involved.

Evidence for MHCs

A number of studies have demonstrated that MHCs' participation reduces recidivism. This effect has been demonstrated in terms of fewer arrests, fewer new charges, and reduced jail time when comparing MHC participants and nonparticipants as well as MHC participants before and after MHC participation. Research has also considered what factors are important for MHC success (i.e., graduation and lower recidivism). MHC participant traits associated with lower recidivism include completion of the MHC program, less substantial criminal history, and older age. Other factors, such as active substance abuse, may be associated with poor MHC outcomes, though findings have not been wholly consistent. In general, studies examining the effectiveness of MHCs on recidivism are characterized by observational designs with small, local samples and limited follow-up periods.

Considerably less research has considered physical health outcomes, though what does exist suggests that a greater percentage of MHC participants receive treatment more quickly than those in traditional courts. Moreover, the cost-effectiveness of MHCs has yet to be widely explored, and current research is inconclusive. Although the justice system can incur reduced costs as participants spend less time incarcerated, treatment costs are often greater for MHC participants, which contribute to mixed cost-effectiveness findings. The cost-effectiveness of MHCs is likely contextually dependent; settings with efficient outpatient treatment systems are more likely to see overall savings compared to settings that depend on local emergency services. As such, further research should consider the potential and expected effects of MHCs from an appropriate systemic perspective.

Future Directions

There is growing recognition in both the social science and legal fields that mental illness interacts with criminogenic risk in complex ways. As such, designing interventions to address the overrepresentation of persons with mental illnesses in the justice system requires an understanding of this relationship. The extent to which there is a synergy between mental illness and criminogenic factors has yet to be explored, and it is likely that interventions for justice-involved persons with mental illnesses will need to utilize multifaceted solutions to address both factors. Given their increasing prevalence across the United States and the growing body of evidence supporting their effectiveness, MHCs represent a promising tool for addressing the mental health needs of justice-involved persons.

Future research should continue to consider what design, process, and participant features are most important for success of MHC. The body of knowledge on MHCs would benefit from more rigorous research designs such as randomized controlled trials or comparative research studies as well as cross-site studies of factors contributing to the effectiveness of MHCs. Future research and quality improvement could also benefit from incorporating broader metrics for success, particularly clinical measures, and the standardization of evaluation techniques. Translating this research into effective and cost-effective practices is also essential, both for existing and for future MHCs.

From a practice perspective, translation of this growing body of research into practice is essential to ensure the long-term viability of MHCs, particularly with respect to their effectiveness. On a systems level, MHCs cannot broker mental health services where no such services exist. Implementation of an MHC without addressing broader problems of the mental health system may jeopardize valuable health and legal resources, and thus any effort to start an MHC should involve a critical appraisal of the current state of local mental health services. Moreover, in communities where community mental health resources are scarce, it could be that MHCs need to provide their own services, such as supportive counseling, case management, or brief solution-focused therapies, especially services that address substance use. Thus,

blending service brokerage with service delivery might be a necessary step for MHCs in environments wanting for high-quality, evidence-based mental health practices.

On a policy level, the long-term sustainability of MHCs requires identification of federal, state, and local resources to support the ongoing development and operation of these courts in an increasingly competitive funding climate. Because ownership of MHCs lies at the interface of the criminal justice and mental health systems, the timeless issue of *who benefits and who pays* is at play here. That is, the criminal justice system benefits from MHCs by diverting persons with severe mental illnesses from the jail into treatment, whereas the mental health community must find a way to serve these individuals, many of whom come without insurance or an ability to pay out of pocket.

In addition, although some guidelines exist on the ideal structure and operation of MHCs, growing research on the key features of MHCs may necessitate a reconsideration and revision of best practice guidelines. Finally, local and state policies are needed to foster data sharing and communication between MHCs, jails, probation and parole, and mental health authorities and providers. Barriers to communication and data sharing present significant obstacles to coordinating care and treatment to justice-involved persons with mental illnesses.

MENTAL HEALTH TREATMENT

It has become increasingly apparent that persons with mental health problems are overrepresented within criminal justice systems internationally. In addition to the offenders themselves, this reality has important implications for policy makers and

professionals concerned with policing, criminal adjudication, community supervision of offenders, management of correctional institutions, and human rights. Depending on the individual case, mental health problems may be, to varying degrees, an impediment to, a cause, a correlate, or a consequence of interactions with the criminal justice system. Mental health treatment may take many forms but broadly refers to interventions intended to ameliorate problems in thoughts, emotions, and behaviors. Mental health treatment may be offered to address criminogenic factors or to facilitate criminal justice processes, but it may also be offered as an end in itself. This entry introduces the types of mental health problems faced by criminal justice systems, common targets and justifications for mental health treatment, and the types of mental health treatment offered in criminal justice settings.

Estimating the Extent of Mental Health Problems Faced by Criminal Justice Systems

Describing and estimating the prevalence of mental health concerns among criminal justice populations are difficult tasks. Relying on a formal diagnostic system, such as the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* or the *International Classification of Diseases and Related Health Problems, 10th Revision*, can provide a structure but also requires considerable professional resources. Even where sufficient resources are available to arrive at formal diagnoses, questions arise about the relative importance of historical versus current concerns and whether such an approach overlooks significant mental health problems that do not necessarily fulfill diagnostic criteria.

Despite these problems with measurement and definition, various researchers have attempted to estimate the rates of mental health problems among criminally involved individuals. According to a 2017 report from the U.S. Department of Justice, approximately 68% of female and 41% of male jail inmates, and 66% of female and 35% of male prisoners reported having a history of a mental health problem. U.S. data have indicated that offenders serving community sentences are also at elevated risk of mental health problems relative to

the community at large. In Canada, all offenders serving a sentence of greater than 2 years are supervised by a federal agency, the Correctional Service of Canada (CSC). Starting with 2010, CSC stopped reporting rates of mental health problems in their yearly disclosure of statistics, citing difficulties in documenting such concerns. However, the Annual Report of the Office of the Correctional Investigator for 2011–2012 noted that 45% of the Canadian federal offender population received some type of mental health intervention. A study conducted with police detainees in Australia in 2011 found that over half of the sample had a history of receiving mental health services. A 2011 study of Indian prisoners found that approximately two thirds had a current psychiatric disorder. What these examples demonstrate is that despite disparate research contexts and methodologies, mental health problems are common among criminal justice populations.

Justification for and Targets of Mental Health Treatment Among Criminal Justice Populations

Forensic Mental Health Populations

Among particular forensic mental health populations, mental health treatment represents the primary focus of criminal justice interventions. For example, various nations and jurisdictions have developed legislation designed for offenders with a mental illness to receive alternative dispositions and sentences depending on the circumstances of their particular offences. Generally speaking, an offender may be deemed not criminally responsible or not guilty by reason of insanity if it is determined that, at the time of the offense, the offender had a mental disease or illness that impaired his or her ability to understand the nature of the act or that it was wrong. In these cases, offenders are often detained or supervised in the community, with the expectation that they will receive treatment for the mental health problem that led to their offense, in order to decrease or manage their risk to the community if released.

Mental health treatment may also become the primary focus of criminal justice interventions in cases of impaired legal competencies or fitness to stand trial. Persons may be deemed incompetent or unfit to participate in various aspects of

criminal proceedings, whether they are attempting to waive their rights during an arrest, presenting a defense during a criminal trial, or facing execution. In cases in which the accused individual or offender cannot participate in the legal process due to a mental disorder, the process may be halted until such time as competency or fitness can be restored.

Mainstream Criminal Justice Populations

Among offender populations for whom mental health problems were not deemed to have mitigated their criminal responsibility, the justifications for mental health treatment may be less obvious. However, in some cases, mental health care may be indicated as a component of criminogenic interventions intended to reduce the individual's risk for recidivism, facilitate participation in correctional or rehabilitation programming, or improve opportunities for community reintegration. In other cases, mental health treatment is indicated within correctional facilities to improve offenders' institutional functioning or to facilitate operational activities. Even in cases where mental health treatment has no obvious criminogenic justification, access to mental health treatment may be offered as a means of fulfilling offenders' basic rights to healthcare. For example in Canada, CSC is legally required to provide all inmates under its supervision with access to essential mental health services and, in some cases, nonessential services that would facilitate offender rehabilitation. Similarly, mentally ill offenders in the United States are considered to have a constitutional right to basic mental health care. Suicide and self-harming behaviors are also areas of significant concern among offender populations.

Types of Mental Health Treatment

Medication

One of the major forms of mental health treatment for criminally involved individuals is psychiatric medication. There are many classes of psychiatric medications, which may be used to increase or stabilize moods, reduce acute or chronic problems with anxiety, improve attention and concentration, or manage aggression. Antipsychotic medications are often used to treat

offenders who have psychotic disorders characterized by hallucinations or delusions, which are common among offenders found not criminally responsible or not guilty by reason of insanity. Antilibidinal drugs may also be prescribed to individuals for whom inappropriate or excessive sexual behaviors are an area of concern.

While the uses and purposes of psychiatric medications are similar among community and criminal justice populations, criminal justice settings present a number of unique considerations. For instance, substance use problems are more common among criminal justice populations, and a number of psychiatric medications have the potential to be abused. Within correctional facilities, psychiatric medications have the potential to be misused or to become part of the illicit exchange of goods and services among inmates. Another issue is that within correctional facilities, the effective and timely administration of medications may be impacted by security, operational, and staffing considerations. For example, professionals' ability to distribute fast-acting medications in times of crisis may be impeded during times of increased security restrictions. Thus, the selection of medications requires the medical practitioner to be mindful of various factors beyond the symptoms that the individual reports.

Primarily Psychological Interventions

In addition to psychiatric medications, much of the mental health treatment offered to criminal justice populations takes the form of psychological or behavioral interventions. Cognitive behavioral therapy (CBT) is one of the most commonly used and validated approaches to mental health treatment, both in the community and among offender populations. This approach emphasizes interactions among one's thoughts, behaviors, and emotions. Cognitive behavioral interventions involve assisting individuals in gaining insight into and challenging their own irrational or problematic thoughts. For example, an offender presenting with depression and anxiety about her probability of success upon release may magnify the importance of her past failures and minimize her previous achievements. To address her emotional disturbance, a CBT practitioner might focus on assisting this individual to arrive at a more

balanced view of her positive and negative experiences or arrive at an objective estimate of her probability of success. CBT has received considerable empirical support for its effectiveness with a variety of mental health problems, including mood and anxiety-related disorders, and there is emerging evidence to suggest that it can improve outcomes among individuals with schizophrenia and other psychotic disorders.

The relapse prevention approach was developed for use among individuals with alcohol and substance use disorders. It is based on the observation that reducing substance use during a treatment program does not guarantee that an individual will remain abstinent over the long term. The approach involves identifying high-risk situations in which an individual has previously engaged in substance use in the past, or might reasonably expect to do so in the future, and developing a plan for alternative behaviors. Both CBT and relapse prevention have received empirical support for their effectiveness in reducing alcohol and substance use among offender populations, and both have proven superior to punishment.

More generally, behavioral interventions focused on social and general skills deficits have also proven effective among offender populations. Regardless of the specific diagnostic category, some offenders with mental health problems experience problems in social interaction or in completing activities of daily living. Programs focused on improving social skills or general functioning have been found to improve both mental health and criminogenic factors.

Dialectical behavior therapy (DBT) is an intensive intervention designed for persons with severe difficulties in emotion and behavior regulation. In addition to CBT principles, DBT emphasizes mindfulness, distress tolerance, and emotion regulation skills. Evidence suggests that DBT can be used to decrease a variety of psychological symptoms, including suicidal and self-harming behaviors among persons diagnosed with personality disorders. For example, DBT has been implemented within CSC's women's institutions, and outcome data collected and published in 2011 suggested that the benefits included significant reductions in both psychological symptoms and problems with institutional functioning. A systematic review of

interventions for self-harming behavior and suicide among incarcerated offenders, published in 2017, also indicated that DBT is an efficacious treatment intervention.

Mental Health Treatment in Criminal Justice Environments: Special Considerations

An understanding of mental health treatment in criminal justice contexts also requires an awareness of some of the unique practical and ethical considerations relevant to mental health professionals in these settings. For example, treatment providers have to consider questions regarding the identity of their client (e.g., the offender, the courts, the correctional institution, or the public), increased limits to the confidentiality (e.g., security considerations in a correctional environment), and freedom of consent (e.g., offenders required to participate in therapy to obtain a community release).

Conclusions

Mental health problems are common among persons involved with criminal justice systems, and treatment for these concerns is often warranted on criminogenic or noncriminogenic grounds. Treatment can take the form of medications and/or primarily psychological/behavioral interventions. Regardless of the form of the intervention, mental health treatment services offered to criminally involved persons require consideration of the population and setting in question.

MENTAL HEALTH TREATMENT PLANNING

International research evidence has suggested that persons with mental health problems are overrepresented within criminal justice systems. This is a matter of significant concern for professionals and policy makers involved in law enforcement, courts, community supervision of offenders, and the management of correctional institutions. Mental health treatment refers to interventions intended to ameliorate problems in cognitive, emotional, or behavioral functioning. These types of interventions may be offered to persons involved in the criminal justice system to address criminogenic risk factors, facilitate various criminal justice processes, or fulfill basic human rights to essential healthcare. Mental health treatment planning is the process of identifying and prioritizing interventions that correspond to the individual's particular mental health concerns. This entry includes estimates of the extent of the mental health problems faced by criminal justice populations, justifications for and types of mental health treatment, an overview of the basic elements of mental health treatment planning, and unique criminal justice considerations.

Mental Health Problems and Criminal Justice Systems

A number of factors can impede the development of accurate estimates of the number of persons with mental health problems within criminal justice systems. First, mental health problems vary widely along multiple dimensions, including symptomatology (e.g., depressed mood vs. disordered perceptual experiences), severity or degree of functional impairment, and expected course (e.g., remission after a few weeks vs. chronic problems persisting across the life span). Thus, estimates will vary depending on the types of problems included and how they are counted (e.g., a single time-point snapshot vs. counting any historical symptoms). Second, formal diagnoses are imperfect and can be costly to obtain. The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* and the *International Classification of Diseases and Related Health Problems–10th Revision* are widely used and accepted by mental health practitioners. However, use of the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* or the *International Classification of Diseases and Related Health Problems–10th Revision* requires training and thus can be costly in terms of human resources. Finally, in criminal justice contexts, a reliance on formal diagnoses may miss relevant concerns that do not fulfill diagnostic criteria. Thus, arriving at a meaningful estimate of mental health problems is not a straightforward task.

Acknowledging the difficulties associated with measuring rates of mental health problems, existing data can still provide some insight into the extent of these problems in criminal justice settings. In Canada, a 2015 prevalence study indicated that 40% of incoming male federal offenders (i.e., offenders receiving a custodial sentence of 2 years or more) met criteria for a mental disorder (the rate was approximately 70% when antisocial personality disorder and substance use problems were included). The U.S. Department of Justice released a report in 2017 estimating that 68% of female and 41% of male jail inmates, and 66% of female and 35% of male prisoners reported having a history of a mental health problem. High rates of mental health problems have also been observed among criminal justice populations

outside North America, including among prisoners in India and police detainees in Australia. Thus, mental health problems among criminally involved persons represent an international issue.

Mental Health Treatment in Criminal Justice Settings

Justifications for the Provision of Mental Health Treatment

For some individuals, mental health treatment is the main focus of the criminal justice interventions they receive. For instance, in many jurisdictions, an offender may be found not guilty by reason of insanity or not criminally responsible if he or she had a mental illness at the time of the offense that impaired his or her ability to understand the nature of the act or that it was morally wrong. In such a case, the individual may receive a legal disposition requiring detention or community supervision, with the expectation that he or she will be provided with treatment to address the mental health problem that contributed to the offenses. Persons found to have impaired legal competencies or a lack of fitness to stand trial as a result of a mental health problem may also receive mental health treatment. One may be found incompetent or unfit to participate in any one of a number of criminal justice processes, from making decisions to waive certain rights during an arrest, to presenting a defense during a trial, to facing execution. Given that criminal justice processes may be paused until the individual's competence or fitness can be restored, mental health treatment can be offered to restore competence.

For other individuals, mental health treatment is not the primary focus of criminal justice interventions. Nonetheless, mental health treatments may be employed as part of criminogenic interventions to directly reduce risk of recidivism, facilitate participation in other programming, or improve prospects for community reintegration. Mental health treatments for particular problems can also be offered on the grounds that they are considered essential healthcare. In the United States and Canada, for example, correctional inmates are considered to have legal rights to essential and some nonessential mental health services.

Types of Mental Health Treatment Offered in Criminal Justice Settings

Psychotropic Medication

Psychotropic medications are a common form of mental health treatment. Medications vary widely on a number of dimensions, including method of administration (e.g., orally administered pills vs. injections) and intended effects (e.g., increase mood, reduce anxiety, increase concentration). Psychotropic medications are generally prescribed (a) to directly treat mental health symptoms (e.g., hallucinations, delusions) in an effort to restore mental health and reduce symptomatology and/or (b) to behaviorally and emotionally stabilize agitated patients to increase staff and patient safety and institutional security. The net effect of these combined functions is that patients are able to benefit from psychosocial or criminogenic interventions when they are more behaviorally and emotionally stable, and their mental health is less compromised. For instance, antipsychotics (e.g., Risperdal, Seroquel), in addition to treating the symptoms of schizophrenia, may be used to curb impulsivity, aggression, agitation, and angry outbursts. The same may be said for anticonvulsants (e.g., Tegretol, Epival), which have similar stabilizing properties, in addition to being used to treat seizures or to control symptoms of mania.

Psychological or Behavioral Interventions

Other mental health treatments are primarily psychological or behavioral. For instance, some mental health treatment approaches are based on the cognitive behavioral therapy (CBT) model. According to the CBT model, an individual's thoughts, emotions, and behaviors exert reciprocal influences on one another. Following from these assumptions, CBT interventions might focus on assisting a client to identify and alter irrational or problematic thoughts, develop healthier behaviors, or regulate emotions, in order to address a mental health concern. The relapse prevention model is another approach to mental health treatment that was developed for alcohol and substance use problems. Relapse prevention interventions involve the development of an individualized plan comprised of high-risk situations

and corresponding strategies to successfully navigate such situations. It is also common for offenders with diverse mental health problems to demonstrate deficits in social functioning or life skills, which may result from or contribute to their primary concerns. For these individuals, behavioral interventions may be offered to remediate their functional deficits, regardless of the underlying mental health concerns.

What Is Mental Health Treatment Planning and Why Is It Necessary?

As mentioned previously, mental health treatment planning involves identifying and prioritizing treatment targets as well as corresponding interventions. While treatment plans will vary depending on the practitioner's specific training and skills, they contain some common elements. Broadly speaking, treatment plans involve the application of a structured or systematic approach to interventions, informed by an assessment of problem areas. These plans require practitioners to explicitly identify what they are doing and why are they doing it. In doing so, practitioners allow themselves to monitor the effectiveness of a given intervention at the level of the individual patient and at the level of a patient population more broadly (e.g., through research evaluations).

Effective and evidence-based treatment plans often require mental health practitioners to obtain and synthesize a broad range of information, from general research trends to more specific data from the individual's personal circumstances. As a result, a case formulation informed by a thorough assessment of the client's functioning is an important element of treatment planning. For instance, the practitioner might consider and explore factors that cause, maintain, or exacerbate particular mental health difficulties, while also considering how various factors interact with one another. Mental health treatment plans based on poor or incomplete case formulations may not only fail to remedy mental health problems, they may actually make them worse. For instance, consider the case of an offender presenting with the following symptoms: low mood, decreased energy, impaired appetite, insomnia, and thoughts of suicide. A practitioner might reasonably conclude that the offender is experiencing a major depressive

disorder, caused or maintained by an organic disturbance in the brain, and prescribe an antidepressant medication to elevate his or her mood. However, if the offender has previously experienced manic symptoms (e.g., elevated mood, inflated self-esteem, risky behavior), it is likely that the depressive symptoms are better understood as part of a bipolar disorder. This additional information would have important treatment implications, given that certain antidepressant medications could exacerbate mental health problems by triggering a manic episode. Thus, an accurate and comprehensive formulation of the individual's mental health problems is a necessary element of treatment planning.

The selection of appropriate and evidence-based interventions is also a critical component of mental health treatment planning among criminal justice populations. Treatments offered to persons demonstrating psychopathic personality traits represent a good illustration of this concept. In the early 1990s, some researchers arrived at the conclusion that mental health treatment offered to psychopathic offenders increased their probability of criminal recidivism. However, in the mid-2000s, a review of the treatment literature suggested that the data were inconclusive in this regard and identified significant problems with the specific intervention approaches that had previously been offered (e.g., the administration of LSD, nude marathon encounter sessions). In contrast, subsequent research studies evaluating treatment programs that target cognitive and behavioral factors that are theoretically and empirically associated with criminal behavior have produced more promising results for reducing recidivism in offenders with psychopathic traits.

Variations in Treatment Planning

Mental health treatment plans can take many forms depending on the mental health practitioners involved in a case, the patient's mental health problems, and the setting, or the nature of the patient's involvement in the criminal justice system. For example, a treatment plan for a case of moderate depression developed by an individual CBT practitioner might involve the following: written homework challenging negative thoughts, education regarding sleep hygiene, and instructions

to engage in exercise. In contrast, a treatment plan developed by an interdisciplinary team (i.e., comprised of various mental health professions) for a not criminally responsible patient with a psychotic disorder (i.e., characterized by thoughts and perceptions that are inconsistent with reality) could include the following: medication to stabilize severely disordered thoughts and behaviors, education and counselling to encourage commitment to treatment, cognitive and behavioral interventions to develop coping strategies for chronic symptoms (e.g., ongoing voices), vocational rehabilitation to increase employability, and clinical discharge planning to establish stable housing and access to professional supports in the community.

Special Treatment Planning Considerations in Criminal Justice Settings

Treatment planning in criminal justice settings can present unique challenges. The following are a sampling of some of these challenges. First, practitioners must often explicitly consider criminogenic factors in identifying appropriate techniques. For instance, they may prioritize the reduction of symptoms that increase the risk of aggression over symptoms that the client finds more distressing. Second, some interventions could be impractical or even harmful in certain settings. For example, behavioral experiments designed to practice social skills or reduce social anxiety may be contraindicated in settings containing high numbers of aggressive and antisocial individuals. Third, many offenders have alcohol or substance use difficulties. This must be considered in dispensing psychiatric medications, which have the potential to become substances of abuse. Fourth, many individuals involved in the criminal justice system present with multiple and complex difficulties (e.g., mental illness, substance use, trauma, a history of head injury, antisocial personality features), making the development of a treatment plan a complicated and difficult task. Thus, to develop effective treatment plans in criminal justice settings, it is prudent to be mindful of assessment practices, emerging research evidence, and the need for flexibility in approach.

MENTAL ILLNESS AND CRIME, ETIOLOGICAL LINKAGES BETWEEN

The issue of whether mental illness and crime are linked has been the focus of mental health and criminological research for decades, coming under increasing scrutiny in the wake of dozens of mass shootings that have occurred since the 1990s because several of the perpetrators had mental health issues. Although such incidents are rare, media attention may help to perpetuate the notion among both the general public and professionals working with this population that mental illness and crime go hand in hand. To truly address this

issue, however, it is necessary to explore the empirical literature that examines the etiological linkages between crime and mental illness so as to promote better prevention and intervention efforts and implement well-informed policy.

Before proceeding, it is important to define what is meant by mental illness, crime, and etiological linkages. With respect to mental illness, this entry focuses on only those diagnosable psychiatric disorders that have been shown to cause severe functional impairment in persons who experience them; these include disorders such as schizophrenia (and other psychotic disorders), bipolar disorder, and major depressive disorder. In this entry, these disorders are referred to collectively as *severe mental illnesses* (SMI). Crime, as it is discussed in this entry, refers not only to general criminal offending but also to violent behavior, one of the more extreme forms of antisocial and criminal behavior. The research that has informed understanding of the mental illness–crime link has utilized official criminal records, self-reports, and institutional records as indices of crime and violence involvement. Finally, when referring to etiological linkages, this entry focuses on associations between the two constructs. Because human behavior, particularly criminal behavior, is vastly complex, it is quite difficult to say that any one factor is a *cause* of crime. As such, SMI is viewed in this entry as a risk factor. Throughout this entry, the reader will be exposed to what the current and most methodologically sound research available has concluded about the relationship between mental illness and crime.

Establishing a Basic Relationship Between SMI and Crime

One of the most basic ways to investigate whether crime and mental illness are related is to simply observe the co-occurrence of SMI and criminal behavior. It may be unknown whether crime preceded mental illness or vice versa, but both have occurred at some point in an individual's life. To put base rates of criminality among those with SMI in context, one needs to know whether people with SMI engage in more, less, or about the same amount of crime and violence as people without SMI. Epidemiological studies suggest that a very small proportion of people in both groups

commit violence and that the rate of violence is slightly higher among people with SMI (e.g., ~3% to 7%) than people without SMI (~2%). When examining just those with SMI, there are some important third variables that exacerbate this risk, such as co-occurring substance abuse, noncompliance with psychiatric medication, and positive symptoms of psychosis (e.g., delusions and hallucinations, particularly threat/control-override [TCO] symptoms).

Supplementing the aforementioned nationally representative epidemiologic surveys are several smaller scale prevalence studies of SMI within correctional populations. Findings suggest that people with SMI are overrepresented among criminal justice populations; that is, the base rate of people with SMI in jail, prison, and community corrections is about 2–3 times as high as the base rate of people with SMI in the general population. Research in correctional contexts suggests that approximately one fifth of those who are under correctional supervision have SMI.

Although these prevalence and epidemiological studies suggest a clear association between mental illness and crime, it is unwise to conclude that mental illness is a cause of crime, simply because these variables appear to be related. In fact, meta-analytic findings suggest that clinical factors such as psychiatric diagnoses and treatment history actually have a negative association with criminal recidivism. A slightly more advanced way to study the mental illness–crime link is to establish ordering. In other words, it is important to demonstrate that the symptoms of mental illness precede criminality. The next section offers a brief review of the evidence that seeks to establish the ordering of mental illness prior to the criminal behavior.

Determining Whether Mental Illness Occurs Prior to Criminal Behavior

For studies to conclude that mental illness leads to criminality or determine that mental illness is a strong epidemiologic risk factor for criminal behavior, research must establish that mental illness precedes criminal behavior. To establish this ordering effect, researchers have examined detailed accounts of particular criminal acts, both as reported by the offenders themselves and as recorded in police records or institutional files. In

each of these studies, researchers reliably coded the antecedents of the criminal acts committed by individuals who have SMI.

Findings have been largely consistent across researchers, offender subgroups, and contexts: Only for a small proportion of cases (approximately 10%), the criminal act was a direct or indirect result of psychiatric symptoms. Most crimes committed by those with SMI are not influenced or motivated by psychiatric symptoms. Instead, they are motivated by factors not unique to mental illness, such as substance abuse, reaction to provocation, or disadvantage (e.g., survival crime). Moreover, among people with SMI who have committed a criminal act motivated by psychiatric symptoms, many also have committed an act that was not motivated by symptoms. Although there is intraindividual variability within the group who has experienced a symptom-motivated crime (i.e., psychiatric symptoms do not always influence their criminality), there is a substantial amount of consistency among offenders with SMI who never committed a crime that was motivated or influenced by symptoms (i.e., a large group of offenders are repeatedly involved in crime that is not influenced by symptoms). Taken together, these studies suggest that mental illness can play a role in criminality and violence but only for a small group of people, some of the time. In other words, psychiatric symptoms are not a prerequisite for crime and violence among those with SMI.

Although limited in number, some studies have used a longitudinal design to ascertain whether the onset of criminal behavior or psychiatric symptoms occurs first during the life span. Results from this avenue of inquiry indicate that, for some people, criminal and antisocial patterns start before the onset of mental illness. Many individuals have individual and environmental risk factors that place them at greater risk of violence and criminal behavior—regardless of whether or not they develop mental illness later in life. Although some scholars have suggested that early-onset antisocial tendencies may actually be prodromal symptoms of mental illness that manifest later in life, it is yet unknown whether criminality or criminal propensity is a separately occurring phenomena from mental illness or a manifestation of some of the earliest signs and symptoms of mental illness for this group.

For the other group, psychiatric symptoms begin to appear before criminal or antisocial behavioral patterns. However, even though ordering can be established for some offenders with SMI using this life course perspective, the mental illness–crime link is not straightforward. In fact, often, individuals who become criminals after the onset of symptoms also have a number of other general risk factors strongly predictive of crime (e.g., homelessness, joblessness, lack of education, living in impoverished neighborhoods, poor family relationships, abuse, antisocial peers, and substance use) that are not unique to mental illness (i.e., people with and without SMI share the same risk factors for crime). It is difficult for researchers to establish the exact sequencing of these multiple risk factors, and studies suggest that different people have different routes by which mental illness can influence later criminal involvement. It is possible that the general risk factors for crime that are shared with individuals who do not have SMI are either stronger for those with SMI or that people with SMI may be disproportionately exposed to them. Regardless, it does not appear that the symptom–crime link is direct. Instead, symptoms experienced earlier in life may be related to later criminality through many different routes or pathways, and exposure to additional known risk factors for crime only seem to exacerbate this relationship.

Ruling Out Rival Explanations for Crime and Violence

At this point, it can be concluded that the relationship between crime and mental illness is quite complex. When establishing a causal link between two variables, one major methodological concern is ruling out potential third variables, or rival explanations, for the correlation between the two. The best research conducted on the issue to date not only has sought to establish that mental illness (symptoms) occurs prior to the criminal behavior but also employs a comparison of similarly situated (e.g., similar demographics, living situation) individuals without mental illness (as a point of comparison) and accounts for other strong risk factors for crime. The 1992–1995 MacArthur Violence Risk Study is one of the most methodologically rigorous studies conducted to date that examines the mental illness–violence relationship.

In this study, researchers identified a group of individuals with SMI who visited psychiatric emergency rooms and followed up with them in the community at several points throughout the course of the year. Researchers assessed participants' experience with mental health symptoms, their use of substances and involvement in violent incidents from self-report and information gathered from collateral sources (e.g., family, friends of the participants, hospital records). Through interviews, researchers could both order mental illness symptoms and violence and establish the extent to which the former had a direct influence on the latter. Researchers also repeatedly assessed, as a control group, individuals living in the same neighborhoods as the psychiatric sample, which helped account for some key risk factors for both crime and violence. When all else were held equal, people with SMI were no more likely than their neighbors without SMI to be involved in violence. When individuals in both groups used drugs or alcohol, their risk of violence involvement increased, but this risk was significantly higher for the group with SMI. Furthermore, when researchers took a closer look at only the SMI group to assess what symptoms preceded any violent incidents, they found that no symptom unique to SMI preceded violence (e.g., threat/control override, somatization, anxiety, depression), but one symptom not unique to SMI—anger/hostility—did. Even in this methodologically rigorous study, results suggest that mental illness alone does not increase one's risk of violence involvement and that other factors shared with those who do not have SMI seem to drive violent acts.

Treating Mental Illness

A final way to examine whether mental illness is an etiological risk factor for crime or violence is to test whether treating the problem (e.g., symptoms) changes the outcome (e.g., crime/violence reduction). Specialized programs that emphasize psychiatric treatment are able to reduce recidivism for offenders with SMI but not by reducing psychiatric symptoms. One meta-analysis that examined treatments focused on targeting mental health symptoms found that, among the most methodologically rigorous studies, addressing psychiatric symptoms has no significant impact on recidivism for people

with SMI. Instead, several studies indicate that the *active ingredients* in interventions seem to focus factors such as establishing high-quality *dual role* (e.g., firm but fair, caring, trusting) relationships between offenders and practitioners.

Concluding Statements

The body of research that examines the mental illness–crime link is both growing and complex. Nevertheless, two important themes emerge from the findings. First, mental illness rarely influences crime and violence. Most people with mental illness will not commit a crime or become violent. For those who do, antisocial behavior is not usually motivated by psychiatric symptoms. Second, crime and violence among those with mental illness are generally motivated by multiple risk factors that are also shared with people who do not have mental illness. These risk factors may or may not be consequences of mental illness, and the relationship between mental illness, other risk factors, and crime/violence is vastly complex. Rather than oversimplifying the mental illness–crime link, practitioners and researchers should concentrate their efforts on understanding the vastly complex array of risk factors that places anyone—not just those with SMI—at risk of crime and violence

MENTAL ILLNESS AND VIOLENT BEHAVIOR: PERCEPTIONS AND EVIDENCE

The potential association between mental illness and violence has fascinated scholars, jurists, and the public alike for millennia. Indeed, archival evidence indicates that the ancient Greeks considered mentally ill people dangerous, as did early American

settlers. In this entry, the focus is on the link between violence and more serious mental disorders (e.g., psychotic disorders, major mood disorders), rather than the full spectrum of psychopathology, which also includes personality disorders and substance use disorders. It addresses some of the myths about mental illness and violence and presents a synopsis of the vast empirical evidence.

Perceptions of the Link Between Mental Illness and Violence

It was not only the ancient Greeks and early American settlers who feared those with mental illness, it is the contemporary public as well. Evidence suggests that, pan-culturally, people with mental illness experience stigma, and part of this stigma is due to the perception that they are unpredictable and violent. Admittedly, some of the symptoms and associated features of serious mental illness can appear as bizarre—talking to oneself, screaming at shadows, disorganized and stereotypic gestures, and at times unintelligible speech. However, does this make someone with severe mental illness more likely to be violent?

Survey evidence indicates that for as many as 50% of people, some of the first words that come to mind when asked to think about what mental illness means to them are *violent* and *dangerous*. Similarly, people often overestimate the percentage of those with mental illness who are violent. Furthermore, people may frequently seek social distance from those with mental illness. That is, research suggests that a large proportion of people would refuse to allow someone with mental illness to rent a room in their house, date their son or daughter, marry into the family, babysit their kids, or look after their pets. To some extent, this might be due to lack of knowledge and awareness of mental illness, in concert with natural human tendencies to be wary of behavior that is out of the norm. For instance, social psychologists have found that the behavior that does not follow a script often leads to wariness, anxiety, and caution among observers. Even behavior as simple as standing backward (facing away from the doors) in an elevator if alone can lead people who get onto the elevator to react with uncertainty and even fear. Why? Because this violates a very strong social script about how to behave on an elevator.

There is also evidence that many members of the public confuse constructs and terms such as *psychosis* and *psychopathy*. Psychosis is a syndrome or cluster of symptoms that exists in some major mental disorders such as schizophrenia, schizophreniform, or schizoaffective disorders; some major mood disorders such as mania or major depression; and in some substance-related disorders. Common features of psychosis include delusions (fixed, maladaptive, false beliefs that may be bizarre—such as believing that your neighbor is really an alien who wants to kill you) and hallucinations (perceiving external stimuli that are not there—such as hearing voices or seeing people). There are also the so-called negative symptoms of psychosis defined by the absence of typical functioning (e.g., lack of joy and pleasure or anhedonia).

These phenomena are starkly different from psychopathy, which comprises symptoms such as callousness, manipulativeness, lack of empathy, and hostile dominance. Yet, the public widely believes that psychopaths are violent and evil. To the extent that members of the public confuse these constructs, they may also, based on misperception of disorders, believe that people with psychosis are similar to those with psychopathy.

The media might also have a role in creating this fear of people with mental illness. For instance, analyses of print and television media indicate that roughly three quarters of news stories and television shows about people with mental illness portray them as violent. That is, sensational instances of people with mental illness committing horrific instances of violence are the norm, not the exception, in terms of the focus of the news. Rarely are there stories of the millions of people with mental illness who are simply living their lives as best as can, demonstrating resilience, raising families, going to work, and spending time with friends.

A 1996 study by Matthias C. Angermeyer and Herbert Matschinger demonstrated the potential impact of media on perceptions of people with mental illness. These German researchers were studying the issue of social distancing and rejection. Part way through their study, by complete happenstance, there was an assassination attempt of two high-ranking German politicians by a person with schizophrenia. This incident, and the fact that the suspect had schizophrenia, received an enormous amount of media attention. The

researchers were able to extend their study to essentially create a *pre-post* research design and compare the degree of social distancing and rejection before and after the media attention. Not surprisingly, already reasonably high rates of social distancing went up substantially after the media coverage of the assassination attempt.

Evidence of the Link Between Mental Illness and Violence

There are literally thousands of research articles that touch on the link between mental illness and crime or violence. Despite this, there remains disagreement among scholars about the nature of the link. Some scholars argue that there is a very small, if not completely absent or even inverse, association between mental illness and violence. However, the bulk of the literature allows some relatively firm conclusions to be drawn.

It is important to state that there is strong evidence that the majority of people with mental illness are not violent. It is the minority of those with mental illness who act violently. In addition, people with mental illness are more likely to be victimized by violence rather than to perpetrate violence. They are also at very high risk of suicide relative to people without mental illness.

However, there is also evidence—from epidemiology, meta-analysis, and primary studies—that some forms of major mental illnesses are indeed associated with higher odds of violence. But the association is not simple, and there remains more to learn. There has been considerable epidemiological research on the link between major mental illness and violence. Such studies are able to focus on large cohorts of people, sometimes even entire birth cohorts within a population. Such studies, mainly from Europe where better recordkeeping allows this type of epidemiological research, have tended to show that serious illnesses such as schizophrenia are associated with 5–10 times the odds of violence compared to people in the population who do not have schizophrenia.

The proper way to interpret an odds ratio is as follows: The odds of observing violence among those with mental illness are 5–10 times greater than the odds of observing violence among those without mental illness. As such, this statistic, commonly used in epidemiology, is much less concerned

with absolute base rates or frequencies than it is about relative frequencies. Nonetheless, this is considered a robust finding in epidemiology, and it has been observed in a few American studies as well.

The downside of epidemiological approaches is that, while they are strong in capturing many people, often the information about these people is relatively superficial because it is drawn from administrative data registers, which in turn depend solely on the quality and depth of information that is entered into such registers. As such, there may be simple diagnostic information rather than symptom-level information. Similarly, the timing of onset of mental illness relative to onset of violence is hard if not impossible to specify. Contextual variables, such as whether a person was receiving treatment, or was employed, or was in a conflictual relationship, rarely if ever appear in these studies.

Other types of studies support the association, however. A 2009 meta-analysis by Kevin Douglas, Laura Guy, and Stephen Hart reported a mean odds ratio across over 200 studies of roughly 3.5, and median odds ratios of 1.49–1.68. Taking the median odds ratio as a more accurate estimate of central tendency due to the asymmetric distribution of odds ratios, this equates to an increase in the odds of violence given the presence of psychosis of 49–68%. Capturing the variability in findings in the literature, however, this meta-analysis also reported a solid quarter of studies that observed an inverse association between psychosis and violence. That is, despite an overall elevated association, roughly 50 of 200 studies found lower odds ratios for violence given the presence of psychosis. This implies that there might be some features of mental illness itself, or in how it is studied, that lead to lower or higher odds of violence.

This meta-analysis, along with numerous primary research studies, has started to identify moderators of the link between serious mental illness and violence. For example, the association between serious mental illnesses involving psychosis and violence is stronger when measured at the symptom level rather than at the diagnostic level. In particular, the so-called positive symptoms (pathological by their presence rather than their absence) such as delusions and hallucinations are more strongly related to violence than is a mere diagnosis of schizophrenia, schizoaffective, or schizophreniform disorder.

There is also considerable evidence from meta-analysis and primary studies that when mental illness and substance use co-occur, the impact on violence is increased substantially—more so than by the sum of their parts. This suggests that people with mental illness may be particularly likely to be violent if they are also abusing drugs or alcohol. At the same time, it suggests that people with substance use problems may be even more likely to be violent if they have a serious mental illness. Given that both mental illness and substance abuse can act as motivators and disinhibitors for violence, this interactive effect makes sense.

It also appears that who the comparison group is matters when asking, are people with serious mental illness more likely to be violent than those without? As it turns out, those with serious mental illness are likely somewhat less likely, on average, to be violent than those with externalizing disorders, such as antisocial and psychopathic personality disorder, or substance-related disorders. Compared to people with internalizing disorders such as depression or anxiety, however, people with serious mental illness are more likely to be violent. Similarly, compared to people with no disorders whatsoever, elevations in violence for people with mental illness are seen.

It is important to point out that much of this reasoning does not directly address why a person with mental illness might be violent. The link in some cases very well may be indirect. For instance, mental illness is associated with stress, difficulty coping, symptom-related distress, lower levels of social support, relationship problems, and employment problems—all of which also elevate risk of violence in some people. As such, some indirect pathways between mental illness and violence would be expected. For other people, there may be a direct, proximate link between mental illness and violence. For example, a person may have a delusion that her partner or neighbor is trying to poison her and for this reason may take pre-emptive action by striking that person first.

A greater deal of theoretical attention to this complex and important topic is necessary to more fully explicate the link. Professionals responsible for evaluating risk of violence should always consider the potential relevance of major mental illness with respect to violence but should never assume that the mere presence of mental illness indicates higher risk. It is vital to explore whether

mental illness played a role in a person's past violence prior to concluding that it has acted as a risk factor for any given person.

MENTAL ILLNESS AS A PREDICTOR OF CRIME AND RECIDIVISM

A mental illness may be deemed present when an individual demonstrates a pattern of abnormal thoughts, emotions, or behaviors that causes

significant impairment or distress. Crime and recidivism (i.e., repeated criminal behavior) reflect behaviors that are deemed abnormal and that break the formalized laws or rules of a society. Both concepts are broad and capture a diversity of human behavior and experience. While the concepts differ in important ways, a review of mental health, criminal, correctional, and legal institutions suggests that they are also inextricably linked. Given the complexity inherent in the concepts, whether mental illness predicts crime and recidivism is a complex question. This entry includes a review of the research linking mental illness to criminal behavior and a discussion of the place of mental illness among other known predictors of crime.

Public and Media Portrayals of Mental Illness as Cause of Crime

When serious crimes come to the attention of the public, speculation and questions about the motivations of the offender arise. Public discourse often focuses on the mental health of the offender. Consequently, media accounts of crime, trials, and sentencing often communicate implicit and explicit messages about the relationship between mental illness and crime. For example, after several individuals were fatally shot in a movie theater in Aurora, CO, in 2012, much of the media coverage included debates about whether the shooter's actions were driven by a mental illness. Similar public debates occurred in relation to the perpetrator of a series of bombings in Norway in 2011. In Canada, the news media reported extensively on the case of an individual who was found *not criminally responsible on account of mental disorder* for the decapitation of a co-passenger on a bus, in 2008, with reports often focused on whether this individual could ever be safely returned to the community. Research on public attitudes toward persons with mental illnesses has uncovered similar themes. Data from the 1996 General Social Survey indicated that the U.S. public assumed persons with a mental illness (e.g., schizophrenia, substance use disorders) to be at elevated risk for perpetrating violence. Various other studies have produced similar results, suggesting that members of the public tend to endorse a connection between mental illness and violence. Taken together, these news media portrayals and

research findings suggest that mental illness is viewed by many as a potential cause of egregious offending behavior.

Mental Illness Among Offender Populations

Research on the prevalence of mental health problems among criminally involved individuals also raises important questions about the relationship between mental illness and crime. Estimates vary depending on the illnesses being considered and how they are measured, but data obtained from Canada, the United States, and the United Kingdom suggest that observed rates of mental illness are considerably higher among individuals involved in the criminal justice system than the rates observed among the general public. For example, according to the U.S. Department of Justice, in 2005, more than half of all incarcerated individuals in the United States had a mental health problem. It is clear that mental illnesses are prevalent among persons involved in the criminal justice system. However, whether mental illness actually predicts criminal behavior is another matter altogether.

Defining the Predictor: Mental Illness

To empirically evaluate the relationship between a predictor and an outcome of interest, one must first clearly define the concepts that are being evaluated. Consider a researcher who is interested in establishing a link between physical illnesses and mortality; he or she would likely expect different results depending on whether he or she included patients with the common cold or with cancer. Like physical illnesses, mental illnesses vary considerably on a number of important dimensions, including symptoms, severity, and expected course. Generally speaking, mental disorders reflect significant difficulties or impairments associated with a person's thoughts, emotions, or behavior. While a comprehensive discussion of mental disorders and diagnostic systems is beyond the scope of this entry, it is important to bear in mind that mental illnesses are heterogeneous. They reflect problems that vary on a number of dimensions, including whether they last a few weeks or persist across the life span, whether they are associated with increases or

decreases in goal-directed behavior, and whether they primarily impact the individual's internal experiences or the individual's interactions with others. Some of the mental health concerns that have been of particular interest to researchers in this area include psychoses, which are characterized by thoughts and perceptions that are inconsistent with reality, substance- and alcohol-related disorders, and personality disorders, which reflect relatively stable patterns of behavior, such as anti-social personality disorder (reflecting behavior that infringes on the rights of others).

Even research focused on a specific disorder can produce different findings depending on how that disorder is conceptualized as a predictor. For example, some researchers compare the outcomes of participants who have ever been diagnosed with a particular disorder in their lifetime to the outcomes of participants who have never received the diagnosis. Other researchers assess whether a person currently meets criteria for the disorder at the time of the study. Still other researchers may evaluate particular symptoms or acute increases in symptoms. Mental illness is a complex and a multifaceted concept, and the research assessing its value as a predictor of crime reflects this complexity.

Possible Associations Between Mental Illness and Crime

Predictive relationships and statistical associations between variables do not require a causal relationship to be present. That being said, various theorists and researchers have proposed causal links between mental illness and crime; they are discussed here briefly to help the reader understand the diverse findings found among the research literature. Broadly speaking, mental illnesses may contribute to criminal behavior through one of three mechanisms: motivation, disinhibition, or destabilization. Active symptoms of psychosis, for example, could motivate an individual to engage in violent behavior if the individual perceived voices encouraging him or her to act out aggressively. Alternatively, symptoms of mental illness may act as disinhibitors. For example, they may contribute to social isolation or a negative self-concept, thereby reducing the perceived risks associated with robbing a bank. Finally, mental illness

may act as a destabilizing risk factor by simply reducing an individual's ability to solve problems effectively, as a result of disorganized behavior or acute confusion. For example, an acutely disorganized individual may inadvertently provoke conflicts with strangers while demonstrating bizarre behavior in a public place.

Defining the Outcomes: Crime and Recidivism

Adding further complexity to the relationship between mental illness and crime is the fact that criminal behavior is diverse and is often difficult to measure. With regard to the diversity among criminal behavior, consider the differences among these hypothetical offenders: a callous and calculating gang member convicted of a series of violent murders, a remorseful former teacher convicted of a single count of possession of child pornography, a businessperson convicted of tax evasion, and a homeless individual convicted of petty theft from a grocery store. A researcher could reasonably expect a given risk factor to be differentially predictive of these types of crimes.

What's more, deciding how to measure when a crime has occurred can be difficult. Researchers using formal criminal records in their research may miss important data, given that many crimes are never detected by the legal system and given that official charges and convictions may not reflect the true nature of an offense (e.g., plea bargaining, the absence of physical evidence). Numbers of unreported and undetected crimes, sometimes referred to as the *dark figure of crime*, are difficult to estimate, with national surveys in North America demonstrating that as much as two thirds to three quarters of all crime go unreported.

Thus, the types of crimes being predicted, and how crimes are measured, vary across research studies. For example, many researchers make distinctions among violent, sexual, and general offending behaviors. Some studies employ formal charges and convictions whereas others include self-reported or observed behaviors. As a result, the question of whether mental illness is a predictor of crime has necessarily been broken down in the research literature into a series of more specific questions, focused on whether specific

groupings of symptoms or disorders predict specific types of criminal behavior.

Mental Illness as a Singular Predictor of Crime and Recidivism

Some research studies have found little to no evidence for mental illness as a predictor of crime. For example, research based on the landmark MacArthur Risk Assessment Study followed a sample of civil psychiatric patients in the United States after discharge to the community and found that a diagnosis of schizophrenia was negatively associated with violent behavior over a 1-year follow-up period. Other research has also failed to find a significant predictive relationship between clinical variables, including symptoms of a mental illness and violent recidivism among particular offender samples. Furthermore, broad reviews of the risk assessment literature among offender populations have indicated that eight risk factors, often referred to as the *Central Eight*, consistently emerge as the most robust predictors of recidivism and that mental illness is not among them.

On the contrary, there is also strong evidence linking particular mental illnesses or symptoms with particular types of criminal behavior and the commission of new offenses (i.e., recidivism) following release from custody. First, there is strong evidence to suggest that certain personality disorders predict recidivism, specifically, psychopathic personality disorder, antisocial personality disorder, and other personality disorders involving behavioral impulsivity and emotional instability (commonly referred to as *Cluster B*). Second, additional research has demonstrated substance-related disorders (i.e., illicit drug or alcohol abuse) to be predictive of recidivism. A series of studies have demonstrated major mental disorders that co-occur with a substance use disorder, what is known as *dual diagnosis*, to be a strong predictor of recidivism; major mental disorders (e.g., depression, schizophrenia) on their own minus substance-related concerns, however, have increasingly been shown to be weaker predictors of recidivism. Third, research suggests that deviant sexual interests, including disorders of sexual preferences such as pedophilia (sexual attraction to children), are significant predictors of sexually violent recidivism. Finally, meta-analyses combining the results

of many research studies have found a significant, if small, relationship between psychosis and violence on average. That said, the literature on psychosis and violence has also elucidated an important feature of the relationship between mental illness and violence: The observed predictive effects vary significantly depending on the setting, populations, and symptoms in question.

Mental Illness as a Component of Structured Risk Instruments

It is well established that the best known predictors of crime and recidivism are structured risk instruments. Notably, many of the most widely used and validated risk instruments have items that capture mental illness. For example, three instruments that have been found to predict general, violent, and sexual recidivism—the Level of Service Inventory–Revised, the Historical–Clinical–Risk Management–20, and the Violence Risk Scale–Sexual Offender Version—each have an item tapping one or more of the mental illness domains noted earlier. However, even among research studies using structured instruments, the predictive relationship between mental illness and recidivism is complex and variable. Among forensic psychiatric inpatients, for example, research indicates that scales capturing acute symptoms of a mental disorder can predict institutional aggression best over the short term, while scales capturing more stable risk factors (e.g., criminal history) tend to be better predictors of community recidivism over the long term.

Conclusions

Despite the conflicting conclusions drawn by individual researchers in the past, the literature as a whole indicates that specific symptoms and particular mental illnesses can contribute to the prediction of crime and recidivism under certain circumstances. In practice, the risk-relevant aspects of mental illness tend to be assessed using risk instruments that tap a variety of other risk factors. To date, these structured risk assessment instruments have proven to be the best known predictors of crime and recidivism. Given research on public opinions and the stigma associated with mental illness, it is important to note that the

majority of persons with a major mental disorder will not engage in violent or criminal behavior.

META-ANALYSIS

Meta-analysis is a method for statistically combining research results. Prior to the creation of meta-analytic techniques, research was reviewed by reading all articles on a topic and then drawing an overall conclusion. For example, a researcher investigating the relationship between a police officer's age and use of force might search for every study on the topic, count the studies showing significant results, and then conclude, "Because 15 studies showed a significant relationship and 16 did not, it does not seem that an officer's age is related to his or her use of force." However, due to a variety of issues, such as small sample sizes, such conclusions were often wrong.

The goal of a meta-analysis is to arrive at one number, called the *mean effect size*, which

represents the average finding across all studies. This effect size provides an estimate of the magnitude of effect. There are two commonly used effect sizes. The first, a correlation coefficient, is used when the question being asked involves the relationship between two variables. The following are the examples for questions:

- What is the typical correlation between IQ and performance in the police academy?
- What is the relationship between job satisfaction and job performance?
- What is the relationship between age and the ability to detect deception?

The second common effect size, the d (Cohen's d) score, is used when the question being asked involves differences. The following are the examples for questions:

- Are women better than men at detecting deception?
- Are inmates who receive counseling less likely to commit future crimes than inmates who do not receive counseling?
- Are abused children more likely to be violent as adults than children who were not abused?

This entry explains the meta-analysis process and discusses understanding the results of meta-analyses.

The Meta-Analysis Process

Locating Studies

The first step in conducting a meta-analysis is to locate studies on the topic of interest. Typically, there are boundaries applied to this search. For example, a researcher might limit the search by location (e.g., the United States, only English-speaking countries), time period (e.g., studies conducted since 1950), or source (e.g., published journal articles). Time boundaries are usually set when the topic of interest is thought to change across time. For example, a meta-analysis on the effects of working from home would probably only use studies conducted since people commonly used computers, whereas a meta-analysis of sleeping habits might not have a temporal boundary.

In terms of source, some meta-analyses include studies from any source available, whereas others limit the sources to certain journals. For example, a meta-analyst might concentrate his or her search on journal articles and dissertations published between 1970 and 2016 in one of three major journals or referenced in an article published in one of the three journals. In contrast, another meta-analysis on the same topic might include all published journal articles as well as dissertations, conference presentations, and other unpublished studies.

Because there is a tendency for journals to publish articles that have statistically significant results, many meta-analysts contact colleagues to see whether they have conducted any studies on a topic that have not been published. By taking this step, the meta-analyst tries to avoid the *file drawer* problem caused by the bias of not publishing studies finding no statistically significant differences (i.e., studies not published end up locked away in a file drawer).

Determining the Studies to Include in the Meta-Analysis

Once the relevant studies have been located, the next step is to determine which studies will actually be included in the meta-analysis. To be included in a meta-analysis, a study must report the results of an empirical investigation and must include the actual effect size (d or r), another statistic that can be converted into an effect size or tabular data that can be analyzed to yield an effect size. Studies that report results without the aforementioned statistics (e.g., "We found a significant relationship between age and ability to detect deception" or "We didn't see any real differences between our older and younger subjects") cannot be included in a meta-analysis. As a result, there has been an emphasis in recent years for journal articles to contain the information needed for future meta-analyses. This trend is important as authors of older studies commonly included only the statistically significant findings in their tables. As a result, meta-analyses of these older studies would overestimate the average effect size because the smaller effect sizes were left out of the journal articles.

Often, meta-analysts will have other rules about including studies. For example, a meta-analysis on the effectiveness of anger management programs might include only studies using both pre- and post-measures of aggressive behavior and experimental and control groups. These inclusion rules can greatly affect the number and quality of the studies included in a meta-analysis.

Converting Research Findings to Effect Sizes

Once it has been determined which studies are appropriate to include in the meta-analysis, statistical results (e.g., F , t , chi-square) that need to be converted into effect sizes are converted using standard formulas. In some cases, raw data or data listed in tables can be used to directly compute a correlation coefficient or d score.

Cumulating Effect Sizes

After the individual effect sizes have been computed for each study, each effect size is multiplied by the sample size of the study, the products summed, and then the total divided by the total sample size to arrive at a mean effect size. This procedure ensures that larger studies—presumed to be more accurate and stable—carry more weight than smaller studies.

Correcting for Artifacts

In many meta-analyses, the effect sizes are adjusted to correct for error associated with study artifacts such as sampling error, measurement error, dichotomization, and restriction of range. The idea behind these corrections is that the *real* relationship between two variables (e.g., job satisfaction and correctional employee performance) is underestimated because the job satisfaction and performance measures are not perfectly reliable. Furthermore, employees with very high or very low scores are often not in the study (i.e., low performing employees would have already been fired and thus not available to be in the study).

Using the job satisfaction example, artifact corrections allow the meta-analyst to answer the question, “If there was a perfect measure of job satisfaction, a perfect measure of job performance, and no range restriction, what would be the ‘true correlation’ between these two variables?”

Artifact adjustments for predictor and criterion reliability are usually made when the meta-analysis topic is more theoretical than practical. For example, compare a meta-analysis of the relationship between cognitive ability and police officer performance with a meta-analysis of the relationship between a particular cognitive ability test and police performance. In the first example, the variable of interest is a theoretical construct, cognitive ability, whereas in the second example, it is a specific test.

Determining the Presence of Moderators

In an ideal world, the results of a meta-analysis could be generalized across all similar organizations and settings. In meta-analyses, it is common to generalize results when at least 75% of the observed variability in effect sizes can be attributed to sampling and measurement error. When less than 75% can be attributed to sampling and measurement error, a search is conducted to find variables that might moderate the size of the effect size. For example, women might be better than men at detecting deception in friends but not in strangers.

The idea behind this 75% rule is that, due to sampling and measurement error, effect sizes are expected to differ from study to study. The question is: Are these observed differences simply due to sampling and measurement error, or do they represent real differences in studies? That is, Is the difference between the correlation of .40 found in one study and the correlation of .15 found in another study due to sampling error, or is the difference due to the subjects in one study being police officers and the subjects in the other fire fighters?

Understanding Meta-Analytic Results

Table 1 presents the results of a hypothetical meta-analysis investigating the relationship between extraversion and police performance in the academy and on the job. This table is similar to those found in many published meta-analyses.

Number of Studies and Sample Size

The K column contains the number of studies used in the meta-analysis, and the N column contains the total number of subjects across the

Table 1 Hypothetical Meta-Analysis Results for Extraversion

Criterion	K	N	r	95% Confidence Interval		ρ	90% Credibility Interval		Var (%)	Q_w
				Lower	Upper		Lower	Upper		
Academy grades	46	10,447	.08	0.01	0.15	.16	0.06	0.26	77	80.82
Supervisor ratings	69	18,237	.25	0.20	0.30	.41	0.36	0.46	82	71.4

K = number of studies; N = sample size; r = mean correlation; ρ = mean correlation corrected for range restriction, criterion unreliability, and predictor reliability; VAR = percentage of variance explained by sampling error and study artifacts; Q_w = the within-group heterogeneity.

studies. Because the number of available studies varies tremendously across research topics, the number of studies found in a meta-analysis could range from 3 to several hundred.

Mean Observed Effect Size

The *r* column in Table 1 is the mean correlation coefficient across all of the studies (weighted by the size of the sample). This coefficient answers the question, “What is the typical correlation found in studies investigating the relationship between extraversion and police performance?” The hypothetical meta-analysis results in Table 1 indicate that the correlation between extraversion and academy grades is .08 and that the correlation between extraversion and supervisor ratings of on-the-job performance is .25.

Confidence Intervals

To determine whether the average correlation coefficient is statistically significant, we look at the next two columns: the lower and upper limits to the 95% confidence interval. If the interval between the lower and upper limits includes zero, the correlation coefficient is not statistically significant. From the data in Table 1, we would conclude that there is a small, but statistically significant, relationship between extraversion and academy grades and a moderate and statistically significant relationship between extraversion and performance as a police officer.

Confidence intervals allow meta-analytic results to be communicated with a sentence such as, “Though our best estimate of the validity of

extraversion in predicting supervisor ratings of police performance is .25, we are 95% confident that the correlation is no lower than .20 and no higher than .30.” Although the current example used a 95% confidence interval, some meta-analyses use 80%, 85%, or 90% confidence intervals. The choice of confidence interval levels is a reflection of how conservative a meta-analyst wants to be: The more cautious one wants to be in interpreting the meta-analysis results, the higher the confidence interval used.

Corrections for Artifacts

The next column, labeled ρ (rho), is the average correlation coefficient corrected for criterion unreliability, predictor unreliability, and range restriction. This coefficient represents what the *true validity* of extraversion would be if we had a perfectly reliable measure of extraversion, a perfectly reliable measure of academy grades and supervisor ratings of performance, and no range restriction. Notice how the observed correlations of .08 and .25 increase to .16 and .41 after being corrected for study artifacts. When interpreting ρ , it is important to consider how many artifacts were included in the corrected correlation. That is, two meta-analyses on the same topic might yield different results if one meta-analysis corrected for three artifacts, whereas another corrected only for range restriction.

Credibility Interval

Credibility intervals are used to determine whether the corrected correlation coefficient (*r*) is

statistically significant and if there are other variables that potentially moderate the relationship between the variables being studied. As with confidence intervals, a credibility interval that includes zero indicates that the corrected correlation coefficient is not statistically significant. If a credibility interval contains zero or is large, the conclusion to be drawn is that the corrected validity coefficient cannot be generalized and that there may be moderators affecting the relationship.

Percentage of Variance Due to Sampling Error and Study Artifacts

The “Var” column in Table 1 is the percentage of observed variance that is due to sampling error and study artifacts. Notice that for grades and performance, these are 77% and 82%, respectively. Because the percentage is greater than 75, the findings can be generalized and a search for moderators is not necessary.

Rather than using the 75% rule, some meta-analyses use a test of statistical significance. The results of these tests are reported as a Q_w or H_w statistic. If this statistic is statistically significant, a search for moderators is made. If the statistic is not significant, the findings can be generalized. In Table 1, the Q_w statistic was not significant for either academy grades or supervisor ratings of performance. This lack of significance is consistent with the fact that sampling error and study artifacts accounted for at least 75% of the observed variance.

MEXICAN DRUG CARTELS

According to the U.S. Department of Justice, Mexican drug trafficking groups, commonly called *cartels*, pose the greatest criminal threat to the United States. These groups dominate the production and trafficking of most of the illicit drugs that come into the United States. Mexico is a major producer of heroin, marijuana, and methamphetamine and, since the late 1980s, serves as the main transshipment route for South American cocaine reaching the U.S. market.

Mexico's drug cartels have diversified into other criminal activities, but many analysts contend that the largest portion of their profits continue to be derived from the lucrative drug trade. Competition between cartels and armed resistance to a Mexican government crackdown resulted in an estimated 100,000–150,000 organized-crime style homicides in Mexico since 2007.

Are They Cartels?

In the 1980s, the cartel moniker was used to describe the large Colombian drug trafficking organizations. Popular usage extended the term to all major drug trafficking groups outside the United States. Some of Mexico's organizations, in their heyday of the 1980s through the mid-2000s, controlled defined territories, enforced monopoly control over transport routes to the United States called *plazas*, and reduced market competition through bribery and violence. Although they never fixed prices, formally acting as oligopolies, Mexico's drug cartels attempted to insulate themselves from government law enforcement operations to ensure their businesses could flourish in impunity.

Mexico's drug cartels have steadily diversified into other types of crime and extended their activities to some 60 countries across the globe. The larger Mexican cartels are now important actors in *transnational organized crime*.

Background on Drug Trafficking in Mexico

Mexican trafficking of marijuana and heroin (from opium poppies grown in Mexico) into the United States began early in the 20th century. Mexico's drug cartels became entrenched during the one-party rule of the Institutional Revolutionary Party between 1929 and 2000. Alcohol smuggling during the U.S. prohibition was an early criminal activity of the organizations that became the cartels. The Guadalajara cartel was founded in 1980 by Miguel Angel Félix Gallardo, a former police officer from Sinaloa state. His organization spawned a network of traffickers that eventually battled one another and vied to exploit the cocaine trafficking business from Colombia to the United States.

The major Mexican cartels, such as the Gulf cartel, the Arellano-Félix organization, the Beltrán Leyva organization, the Juárez cartel, Los Zetas, and the Sinaloa crime group, sometimes produce and traffic multiple drugs. Some cartels or regional wings of a larger crime group may specialize in a particular drug, such as the now-decimated group called *La Familia Michoacana* that specialized in methamphetamine production in southwest Mexico, although a new transnational criminal organization, the Cartel Jalisco New Generation, has become prominent in the methamphetamine trade.

Since 2006, because of intensified conflicts, these groups have merged or more frequently splintered and have been in a state of almost constant flux. The number of fragmented groups (*cartelitos*) is estimated in 2015 to have grown to between 60 and 200 groups. In 2015 and 2016, the more prominent new organizations that have emerged include the Cartel Jalisco New Generation, Los Viagras, Guerreros Unidos, and Los Cuinis.

In addition to fragmentation, there has been a major shift into other types of predatory crime including natural resource theft (e.g., oil smuggling, illegal logging, and illegal mining), domestic drug sales, kidnapping, human smuggling, and extortion of legal businesses of all types.

There is no agreement on the dollar value of the Mexican drug traffic or the revenues of the criminal organizations. From 2010 and 2011, plausible estimates of Mexican drug-related proceeds were

between US\$4 billion and US\$29 billion. A 2015 study by the Financial Action Task Force of bulk cash smuggling over the U.S.–Mexico border produced a range between US\$6 billion and US\$36 billion annually (with US\$25 billion as a generally accepted figure), but the share returned to the drug cartels is unknown.

Sinaloa Cartel

The Sinaloa cartel controls roughly 60% of Mexico's drug trade overall. Sinaloa rose to dominance through corruption of high-level Mexican officials and violent battles with rivals. Its leaders are Joaquín “El Chapo” Guzmán, who twice escaped from Mexican prisons and was recaptured in January 2016 and extradited to the United States a year later, and Ismael Zambada García. Sinaloa's drug income is derived from cocaine, marijuana, methamphetamine, and also reportedly heroin, having pushed Colombian suppliers from another market they once dominated. It is unclear at what point in heroin production the cartel takes control of the product—at the farm gate or later. Also, Sinaloa's control of wholesaling and retailing of heroin in U.S. communities has been little examined in open-source publications.

Continual Evolution but Violence Remains a Constant

The Mexican cartels have changed their names and alliances regularly. Following a crackdown launched by Mexican president Felipe Calderón in 2006, violence in Mexico related to organized crime and drug trafficking soared through 2011. The security situation stabilized in 2012, and violence declined for a couple of years by roughly 15% a year. However, the murder rate started to rise again in 2015 and reached a record level in 2017.

Exports of heroin have grown dramatically since 2014, feeding a growing demand for opioids in the United States. The U.S. Drug Enforcement Administration reports that fentanyl, a powerful synthetic opioid, is being illegally produced in Mexico and China. Heroin and fentanyl overdoses are contributing to a growing epidemic of fatal opioid overdoses while U.S. cocaine use has

declined. The U.S. market for Mexican marijuana is less profitable due to U.S. state efforts to legalize adult recreational use and to ease other restrictions.

Some analysts suggest that the hyper-violence of the cartels reveals the cartels to share traits with guerrilla insurgents, requiring a military-backed response. However, many analysts counter that Mexico's drug cartels remain fundamentally a crime problem, and the most important tool for effectively combating them is major institutional reform to reduce impunity, lower corruption, and inculcate the cultural and political respect for human rights necessary to establish the rule of law.

MEXICAN MAFIA

The Mexican Mafia is a prison gang, being the first such gang to establish extralegal governance over prison inmates as well as criminal street gangs conducting gang-related criminal operations outside prison walls. It achieved this power and control by offering protection services to incarcerated gang members in return for payment of *taxes* (percentages of criminal profits) and extralegal jurisdiction over the allied street gangs.

This umbrella of protection was first offered for incarcerated gang members but was later extended to include protection services for the allied gang itself, including protection for any allied gang member, regardless of whether the gang member was inside or outside prison walls. Any failure to pay taxes or follow Mexican Mafia orders results in issuance of a *green light* to assault, batter, or kill any and all members of the noncompliant gang.

Through psychological and physical coercion, the Mexican Mafia prison gang became one of the strongest and most feared prison gangs in the United States. More than 400 allied criminal street gangs willingly pay taxes and submit to extralegal governance by the Mexican Mafia. This jurisdiction includes the authority of the Mexican Mafia to resolve issues such as turf ownership, dispute resolution, control of drug trafficking operations, or other gang-related criminal activity. As a result, the Mexican Mafia controls more than 21,000 Hispanic and Mexican American gang members operating in the United States, Mexico, and parts of Central and South America. After reviewing the history and the structure of the Mexican Mafia, this entry explores the gang's extralegal governance and its ability to maintain solidarity.

History of the Mexican Mafia

In 1957, the Deuel Vocational Institution housed some of the worst youthful offenders in California. The inmates would align along racial, ethnic, cultural, or religious ties and prey upon less organized Hispanic and Mexican American inmates. In response, inmate Louis "Huero Buff" Flores founded the Mexican Mafia prison gang. Designed after the Sicilian Mafia, the Mexican Mafia provided social support and protection for the less organized Hispanic and Mexican American inmates. But the goal was more than mere protection and social support: Flores's stated goal was to create an elite *prison gang of gangs* that not only aligned prison inmates but also served to align Hispanic and Mexican American criminal street gangs operating outside prison walls.

The premise was simple. Drug dealers and most gang members realize that they are likely to get caught committing gang-related crimes and are likely to serve time in prison. Once incarcerated, they become prey for more organized groups of

prisoners and prison gangs who are often armed with homemade prison weapons. Because of this vulnerability, the street gangs are willing to align with the Mexican Mafia prison gang, pay taxes, and follow orders issued by the Mexican Mafia in return for protection services.

Organizational Structure of the Mexican Mafia

The Mexican Mafia does not have a rank and file. In prison, each Carnal (i.e., full pledged member) has one vote, with each vote being equal. This organizational structure provides insulation should a Mexican Mafia Carnal be relocated, die, or be killed by rival prison gang members.

Due to a continuous supply of inmates, the loss of a few Carnals does not threaten or cause collapse of the Mexican Mafia prison gang. Instead, many inmates line up to become Mexican Mafia prospects. As a measure of precaution, the Mexican Mafia performs extensive background checks on prospective members. In addition, any prospect must abide by the Mexican Mafia *regales* (rules) and follow orders for approximately 2 years before being considered for full membership as a Carnal. Upon completion of the initiation phase, the prospect must attain unanimous approval of all sponsoring Mexican Mafia Carnals. This thorough initiation process makes it highly unlikely that the Mexican Mafia will be overthrown by a rival prison gang or infiltrated by an undercover law enforcement officer.

During the initiation phase, the prospect must pledge allegiance to the Mexican Mafia, follow the Mexican Mafia *regales*, and abide by the Mexican Mafia Constitution. To show bravery and loyalty to the Mexican Mafia, the prospect is required to physically attack or kill another inmate. The Mexican Mafia has established a “blood in, blood out” initiation oath, whereby a prospect must draw blood or shed blood to become a member.

Loyalty to the Mexican Mafia is also for life. All prospects and members are duty bound to attack anyone who does not display proper respect to the Mexican Mafia. Should a Carnal or associate become disloyal, all Mexican Mafia members, prospects, associates, and allied street gangs are duty bound to kill that disobedient individual.

Psychological Coercion

Understanding the Mexican Mafia’s vast network of control and extralegal governance of allied criminal street gangs requires an understanding of the nature of incarceration. A newly incarcerated individual is stripped of personal belongings, weapons, and any protection afforded by fellow street gang members remaining outside prison walls and is thrown into unfamiliar surroundings, most frequently a cell or barracks. Being alone, the inmate becomes prey for more organized, predatory inmates.

In part, it is a numbers game. Most street gangs (as opposed to prison gangs) have fewer than 40 members. As such, it is unlikely that more than three or four members of the same street gang will be incarcerated in the same prison at the same time. As a result, most incarcerated gang members are outnumbered by the more organized inmates or rival prison gangs. These prisoners and established prison gangs pose serious physical threats to a new inmate, as they are often armed with homemade prison weapons and are familiar with blind spots in the prison yard where they can victimize a new inmate without detection.

Consequently, incarcerated street gang members face a choice: either join a prison gang or become prey for roving bands of prison predators. The street gangs have a similar choice: either align with a prison gang or watch helplessly as their members are victimized, harassed, or even killed once inside prison walls. The allied street gangs willingly pay taxes and submit to extralegal governance by the Mexican Mafia prison gang to ensure their own protection.

Mexican Mafia Solidarity

The Mexican Mafia Constitution further establishes solidarity. It affirms that “the Mexican Mafia comes first—even before your own family.” As a condition of membership, gang members must lay aside any former gang rivalries or personal conflicts to further the interests of the Mexican Mafia. Since membership is for life, this remains true regardless of whether the Mexican Mafia member is inside or outside prison walls. The number one priority must be the Mexican Mafia, and the number one goal must be to further Mexican Mafia criminal interests.

Furthermore, the Mexican Mafia solidarity is synergistic. Through a pledge of absolute loyalty to the Mexican Mafia, the gang psyche strengthens any individual weaknesses, making each gang member bolder, braver, and stronger than if acting alone. Carnals, associates, and allied street gang members are willing to take risks, knowing that the entire Mexican Mafia, including 21,000 Sureño street soldiers and 1,500 associates, will back them if conflict arises. As such, the Mexican Mafia and allied street gangs act as a collective that is unified and ready to attack if confronted with disrespect, insubordination, or violence.

This solidarity serves to strengthen power and control over allied street gangs. As noted earlier, allied street gangs are willing to pay taxes, ranging between 10% and 30% of the street gang's criminal profits, to become a member of the elite *prison gang of gangs*. If the taxes are not paid, the Mexican Mafia issues a green light for all Mexican Mafia members, associates, and aligned street gangs to attack and take over the noncompliant gang's street territory and criminal operations. Without the Mexican Mafia's protection, the green light makes the noncompliant street gang vulnerable to overthrow by a rival street gang, resulting in a loss of gang-related profits or gang-related territory, or both. Accordingly, allied street gangs seldom fail to pay taxes to the Mexican Mafia.

Solidarity is also strengthened once a Mexican Mafia member or associate is released from prison. Association with the Mexican Mafia is viewed as a status symbol and most often allows the released inmate to assume a position of leadership in the former street gang. In some instances, the Mexican Mafia Carnal rejoins the street gang as a tax collector who secures payment of taxes to the Mexican Mafia prison gang. Through this symbiotic relationship, power and control over aligned street gangs are further strengthened, and Mexican Mafia solidarity is enhanced.

Power and Control Over Street Gangs

As noted, the Mexican Mafia is solidly entrenched in U.S., Mexican, and Central American prison systems. It stands strong with more than

400 members, at least 1,500 prison associates, and more than 21,000 Sureño street gang members (soldiers) that stand in alliance with the Mexican Mafia. As a result of such numbers, most street gangs are without sufficient numbers to pose a threat to Mexican Mafia control.

This is evidenced by the 1992 conflict when the Mongols outlaw motorcycle gang refused to pay taxes to the Mexican Mafia. As a show of force, the Mexican Mafia issued a green light on any Mongol gang member. Once the green light was issued, all Mexican Mafia members, associates, and Sureño soldiers were obligated to enforce the green light through acts of violence, regardless of whether the Mongols were on the streets or behind prison walls.

On the streets, the well-organized motorcycle gang of approximately 2,600 members was able to fend for itself. However, the same was not true inside prison walls. Incarcerated Mongols were severely outnumbered and became targets for harassment, physical violence, and murder. The only alternative to continual harassment was to seek protective custody that afforded 23-hr lockdown. As a result, the Mongols submitted to taxation and control by the Mexican Mafia 1 year after the Mexican Mafia's display of violence and aggression.

Mara Salvatrucha also refused to pay taxes to the Mexican Mafia. In retaliation, the Mexican Mafia issued a green light on all Mara Salvatrucha gang members, regardless of whether the Mara Salvatrucha gang members were inside or outside prison walls. The unending harassment disrupted business and recruiting efforts to the point that Mara Salvatrucha agreed to pay taxes and align with the Mexican Mafia. As a sign of allegiance, Mara Salvatrucha added the Mexican Mafia identifier "13" (representing the 13th letter of the alphabet or "M") to their name, thus acquiring the notorious nickname "MS-13."

Emergence of Other Prison Gangs

Once the Mexican Mafia emerged, other prison gangs followed. Similar to the Mexican Mafia, these prison gangs initially formed to provide social support and much needed protection from harassment or physical violence. But once the

prison gangs became established, the focus shifted from social support and protection to gang-related profits and organized crime. They engaged in extortion of taxes and more control of gang-related criminal activity, both inside and outside prison walls.

One such example of a well-established prison gang is the Nuestra Familia prison gang. It was established in the 1960s to provide protection for Hispanics and Mexican Americans incarcerated in Northern California prisons. Since Norteño street gangs (located in Northern California) are hostile enemies of Sureño street gangs (located in Southern California), Nuestra Familia served as an alternative to joining the Mexican Mafia, especially since the Mexican Mafia is highly saturated with Sureño street gang members.

Since the 1960s, the Nuestra Familia prison gang has become a very powerful prison gang not only in Northern California prisons but also in the southern and Western states. It exerts extralegal jurisdiction over approximately 1,000 allied criminal street gangs (primarily Norteño street gangs), both inside and outside prison walls.

Similarly, the Barrio Azteca in Western Texas, the Mexikanemi in Southwest Texas, the United Blood Nation in New York, and the Black Guerrilla Family in Maryland are examples of well-established prison gangs that provide protection services for inmates and allied street gangs in return for extralegal governance and payment of taxes.

With growth, alliances naturally form. For example, the Mexican Mafia aligns with the Aryan Brotherhood, and the Nuestra Familia prison gang aligns with the Black Guerilla Family. Such alliances, both inside and outside prison walls, serve to enhance criminal operations such as smuggling inside prison walls and drug trafficking operations on the streets.

Solidarity Through Segregation

The rules and regulations of the correctional systems in the United States may serve to strengthen solidarity of the Mexican Mafia and other prison gangs. Generally, rival gang members are not placed in the same prison cells or pods. Instead, rival gang members are most often housed in segregated units. Because gangs generally align along

racial, ethnic, and cultural ties, this segregation often perpetrates growth of new prison gangs and serves to strengthen solidarity and loyalty to existing prison gangs.

To compound the issue, correctional facilities are seldom able to control all aspects of inmate conduct. Budgets and lack of correctional officers minimize the extent of such power and control. Moreover, inmates and prison gangs seldom look to correctional officials or the judiciary for protection or dispute resolution. Instead, the prison evolves its own prison culture and its own governing system, with prison gangs often serving as the governing bodies that provide extralegal governance, protection services, and dispute resolution. The prison gangs become pseudo-governments that further spawn their growth, expansion, and control.

Furthermore, prison gangs make it clear that a green light will be issued if their orders are not followed. As a consequence, decisions of these extralegal governing bodies are most often upheld. Otherwise, incarcerated members of aligned gangs risk daily brutality, loss of life, and an almost unbearable prison existence. As a result, this physical and psychological coercion makes any prison sentence, even a short sentence, extremely difficult.

Conclusion

The Mexican Mafia has become one of the most feared and violent prison gangs in the United States. Its span of control encompasses not only U.S. prisons but also prisons in parts of Central and South America. As such, the Mexican Mafia is not only a growing concern for correctional officials but also a growing concern for federal and state law enforcement agencies throughout the United States.

MILITARY SERVICE SCREENING

Military personnel are responsible for the defense of the nation, and military service is physically and mentally demanding. Successful adaption to military service requires a high degree of physical and psychological health and fitness, aptitude for specialized education and training, and the personal resources to uphold good order and discipline and tolerate the hardships associated with military service, including combat. Unsurprisingly, many individuals fail to complete their first assignment, and for the majority, this is a result of adjustment and behavioral issues. Consequently, the U.S. military uses employment-screening procedures to evaluate an individual's trainability and potential to successfully adapt to the unique demands of military service. Personnel are screened prior to entry into service to determine eligibility for critical and sensitive positions as well as to determine suitability for high-risk, specialized military duties (e.g., Special Operations Forces [SOF]). This entry describes the processes typically used to screen candidates at each of these points, with an emphasis on psychological standards and screening methods.

Psychological Screening for Entry Into Military Service

The U.S. Department of Defense sets by directive the minimum qualification standards for entry into service to ensure that recruits are able to successfully adapt to service and perform military duties. Individuals desiring to enter military service must meet exacting aptitude, medical and physical, and conduct/behavioral standards. Requirements for some of the branches of the Armed Forces may be more restrictive than the minimum standards, especially with respect to drug and alcohol use and character and conduct problems.

Aptitude

Screening for aptitude has been employed in military entry procedures since World War I and grew out of the exigencies of having to screen large numbers of draftees for the war. Intelligence tests, newly developed at that time, allowed for rapid and effective ability screening. The Armed Forces Qualification Test (AFQT), derived from the Armed Services Vocational Aptitude Battery, is now used to assess eligibility to enlist and facilitate appropriate career placement. Educational level and AFQT scores predict training success and completion of a service term and are used together to determine eligibility for service. For example, an individual who has not completed high school is ineligible for military service unless that person scores at or above the 31st percentile on the AFQT. Certain military occupational specialties involving highly technical training are not open to individuals scoring below specified AFQT scores. Of note, the AFQT is used for enlistment purposes only; there is no one specific aptitude measure used for appointment as an officer in the military.

Medical and Physical Standards

All service members must be medically, psychologically, and physically fit for deployment regardless of job classification, as all may be required to put themselves in harm's way. Each of the services has established medical standards, and applicants are screened for disqualifying medical and mental health conditions with a

general medical examination at entrance. There is no psychiatric evaluation; rather, mental health is screened by a medical history form completed by applicants. History of severe mental health disorders, such as psychoses, severe mood and anxiety disorders, and substance use disorders are disqualifying, as are history of conduct disorder and suicide attempts. Some disqualifying mental health conditions may be eligible for waiver, but such waivers are difficult to obtain.

Currently, there is no formal testing for physical fitness at entry, but all recruits must meet minimum height and weight standards. All individuals are required to pass stringent physical fitness tests to successfully complete basic military training.

Conduct and Behavior

Military service requires discipline as well as the ability to conform oneself to rules and standards. Applicants are screened for past legal and conduct issues in order to minimize the entrance of individuals who are likely to be a security risk, or may disrupt moral, good order, and discipline. Services collect fingerprints at entry and conduct a criminal background investigation. U.S. Code (Title 10 §504) prohibits anyone convicted of a felony from entering military service. In exceptional circumstances, this may be waived; however, individuals convicted of a sexual offense are prohibited from entering service. A pattern of antisocial behavior reflected by repeated legal encounters or conduct problems reflecting difficulty conforming to legal or moral standards, immaturity, or poor impulse control may also render an individual unfit for military service. Any pattern of drug or alcohol abuse or dependency is medically disqualifying. Illegal drug use that is habitual, or involves drugs other than marijuana, as well as a positive test for certain illegal drugs during the enlistment process is disqualifying for military service and requires review and waiver to enter service.

Screening for Special Military Duties

There are some jobs within the military that require specially screened personnel because of the skills and training and the psychological

competencies required to perform them successfully. Military aviation is a prominent example. Others require access to classified programs and information.

Military Aeronautics

Pilot training is the most expensive training in the military, and military aircraft are among the most technologically advanced and expensive pieces of equipment in the nation's arsenal. Pilots in the U.S. Air Force, Navy, and Marine Corps are all commissioned officers, whereas the U.S. Army uses both commissioned officers and warrant officers. All commissioned officers are required to have a bachelor's degree. Educational requirements differ for warrant officers, who are not required to have a college degree upon entry into flight school.

Regardless of education, all pilot applicants in the military must demonstrate flight-training aptitude. This is assessed using specially developed aviation selection test batteries tapping a number of cognitive abilities relevant to flying (e.g., spatial, psychomotor, mechanical). These tests have been shown to predict success in flight training. In addition, pilot candidates must be medically qualified for flight duties, and pilot candidates must pass special medical evaluations. There are no specific psychological screening measures used, but flight surgeons assess interest in, and psychological suitability and motivation for, military aeronautics in their medical evaluation of pilot candidates.

Critical and Sensitive National Security Positions

Certain positions within the U.S. military involve duties that are sensitive and critical to national security. The positions include access to classified information and programs (Personnel Security Programs) as well as those associated with nuclear weapons (Personnel Reliability Program; including nuclear submarine duties and nuclear missile operations and defense). Personnel must obtain and maintain a security clearance in order to perform these duties, and special screening is required to ensure that such individuals are psychologically stable, reliable, and trustworthy.

An extensive background investigation is used to determine eligibility for entry and continued participation in these jobs. In some instances, polygraph examination may also be required.

Personnel complete the Questionnaire for National Security Positions to begin the investigative process known as a *Single Scope Background Investigation*. This intensive investigation involves a personal interview covering personal, sexual, and criminal conduct; finances and credit; alcohol and drug use; psychological conditions; and importantly, foreign interests and allegiance to the United States. Agents conduct checks of employment, education, organizational affiliations, and criminal records. They also interview coworkers, friends, neighbors, and employers.

Adjudicative guidelines are used to determine eligibility requirements for a security clearance, which is a prerequisite to qualifying for any of these high-reliability positions. An individual may be disqualified if findings from the investigation reflect a recent or recurrent pattern of poor judgment or irresponsible or unstable behavior. Of note, historical or current mental health counseling is not a basis for ineligibility but will result in further inquiry to assess risk factors relevant to suitability for these programs. In addition to the screening requirements, individuals are continuously monitored for their continued suitability for such duties.

Screening for Suitability for Special Military Units

Although all military personnel might be expected to deploy into harm's way, there are certain specialized personnel (e.g., SOF, bomb disposal personnel) who routinely perform high-risk missions under conditions of extreme threat, often with dire consequences for mission failure. Some, such as SOF personnel, deploy frequently to hostile environments and operate highly autonomously, with little tactical or logistical support. These forces often confront novel, complex, and ambiguous military situations requiring them to be tactically competent and agile. They are specially selected and highly trained, possessing technical and psychological competencies beyond those of their peers. Among the essential competencies

required for successful SOF personnel are high stress tolerance, emotional stability, adaptability to rapidly changing demands, teamwork, and sound judgment and decision-making.

Assessment and Selection (A&S)

Personnel who volunteer for these special military assignments must complete stringent A&S programs. These assessment programs represent the most intensive physical, medical, psychological, and occupational screening efforts in the U.S. military. The methods used by A&S programs descend from those used by the Office of Strategic Services to screen clandestine intelligence operatives during World War II. Modern military A&S programs are physically and psychologically rigorous events designed to both screen out those who are unsuited for the work and identify those with the most potential to perform effectively in the job.

A&S programs are structured to mimic the harsh operational environments these military personnel will find themselves in and use demanding physical events (e.g., obstacle courses, ruck marches, swims) as situational tests. In addition to these physical challenges, sleep and food deprivation are used to test performance under extreme physiological and psychological depletion. These rigorous physical demands assess tolerance for hardship, perseverance, and effective performance under stress. Assessment methods also include detailed psychological evaluations (cognitive ability tests, personality tests, and psychological interviews) and situational tests (team and individual). The use of situational tests (or simulations) closely follows the assessment center model, with tasks designed specifically to assess the unique job demands and competencies required for success in a given position. Thus, the content of these tasks differs in A&S programs for various specialized personnel depending upon unique mission and job requirements. However, the psychological screening processes used in various military A&S programs to assess suitability are similar and comprise interviews, cognitive tests, and personality tests.

Psychological Interview

The interview informs the overall assessment of suitability focusing specifically on the candidate's psychological and emotional stability, training

and performance potential, and behavioral and security risks. Interviews often focus on motivation for the job; learning capacity as reflected in past academic and military training and job performance; lifestyle and relationship stability; legal, moral, and ethical behavior; and psychological competencies, including resilience and emotional stability.

Cognitive Testing

The training and operational requirements for these positions demand strong cognitive and intellectual abilities. As in the general work world, cognitive ability proves to be a strong predictor of future training and job performance success in personnel for special military missions. In A&S programs, assessment of cognitive ability is most commonly accomplished using group-administered, well-validated, and usually brief measures of general cognitive ability, such as the Wonderlic Personnel Test or the General Ability Measure for Adults.

Personality Tests

Personality tests are used in the detection of psychopathology to screen out unsuited individuals and in the assessment of general personality traits thought to be important in the work world in general (e.g., conscientiousness) and in the performance of high-risk military duties. Given that emotional stability is a major competency required for success in high-risk military operational personnel, A&S programs routinely incorporate clinical personality instruments. Clinical instruments (e.g., Minnesota Multiphasic Personality Inventory) assist in the detection of psychopathology and are generally used to screen out individuals who are unsuitable for assignment. Tests of personality traits, such as the NEO Personality Inventory–Revised (which corresponds to the Five Factor Model of Personality), are often used to assess desirable personality qualities for success.

MINDFULNESS

Mindfulness is the practice of actively paying attention to the present moment without judgment and with acceptance. As a practice, it involves building attentional awareness through various forms of meditation *and* practicing attitudes that support emotional balance, thought reframing, tolerance, and compassion for self and others. When practicing mindfulness, attention is on accepting the present moment as it is, without judging the events in the moment as good or bad, the associated feelings, or the thought commentary running through the mind. It is being present with oneself and the world with open attention and acceptance. In this entry, mindfulness is introduced first as meditation and then as a complementary therapy for medical problems, stress reduction, substance abuse, and psychological problems, followed by a brief review of the research. The entry closes with an application of mindfulness to the lives of incarcerated people.

Mindfulness as Meditation

Mindfulness has many applications. At its simplest, mindfulness is the practice of meditation, whereby the objective is to cultivate present moment awareness. This is achieved by sitting quietly and focusing attention on the movement of the breath, the beating of the heart, or some sound or image. Learning to redirect attention and maintain awareness is the goal. Mindfulness also can be practiced while active. Yoga is often included in the practice of mindfulness. Yoga, as meditation, is the process of focusing attention on the synchronized movement of the body with the breath. Mindfulness also can be practiced as one actively lives. Here, attention is on being fully present in the moment and letting go of strong attachments to desires, beliefs, feelings, and thoughts. Just letting life be and observing all the moment-by-moment choreography is the practice of mindfulness.

Mindfulness and Stress

Life is stressful. What this means is that through the process of living, humans are exposed to internal and external signals, referred to as *stressors*, which trigger the body and mind to go into a state of alert. These stressors signal danger, independent of whether the threat is real or imagined. In response, the body and mind prepare to meet the danger by producing chemical reactions (a stress hormone called *cortisol*) that generate a protective response, referred to as the *fight, flight, or freeze response*. In general, healthy levels of stress (or eustress) enhance performance and productivity, while unhealthy levels manifest as fatigue, irritability, emotional flooding, exhaustion, ill health, and incapacitation.

Research has increasingly focused on the harmful effects of chronic stressors on health and psychological well-being. When the body's stress-response system is chronically activated, the body is overwhelmed by its own production of stress hormones, which taxes the human immune system, and increases the likelihood of a variety of problems including anxiety, depression, digestive problems, heart disease, sleeping disorders, and memory and concentration problems.

Mindfulness-based stress reduction (MBSR) was created by Jon Kabat-Zinn to help people

with medical problems (e.g., chronic pain, cancer, hypertension, diabetes) use their internal resources (e.g., attention, judgment, acceptance) to respond mindfully to symptoms of illness. The logic of MBSR is as follows: Illness (the stimulus) creates a reaction: stress; the resulting stress (e.g., worry, anger, anxiety) is hazardous to the body and mind and can directly and indirectly exacerbate initial health problems and lower overall well-being. Importantly, between the stimulus and reaction is a choice: to react or not. The client, mindful of the moment and decisional space, can choose to react (impulsively/reflexively) or respond (nonjudgmentally/thoughtfully). For this reason, MBSR is considered a client-empowering intervention. Through mindfulness, clients become aware of these choice points and learn to respond with equanimity and balance. Learning to stop and take a breath or two before responding nonjudgmentally to stimuli is a central feature of mindfulness. MBSR, a combination of mindfulness meditation and yoga, is a group-based intervention delivered over 8 weeks and includes weekly sessions of 3 hr: guided mindfulness exercises, yoga exercises; self-practice; and a daylong retreat. It has been completed by over 22,000 people and is now offered at more than 300 health-care settings.

Mindfulness-Based Therapy

Mindfulness principles have been used to relieve psychological symptoms related to depression, anxiety, and panic. Mindfulness-based cognitive therapy, an 8-week intervention, is designed to prevent relapse of depression. The goal of mindfulness-based cognitive therapy is to help clients develop a practice of meditation that is centering and empowering. Through yoga and meditation practice, clients develop an ability to disengage from reactive and troubling thoughts and feelings and refocus internally on their sense of being, which is separate from thoughts and feelings. Attention is placed on organic changes within the body and mind that are realized through the movement of yoga, breathing, and meditation. At its core, the practice is considered empowering because clients choose to separate from moods and habit thinking and embrace other dimensions of the present moment. By being aware of the separation, clients can actively respond by

nurturing hurtful feelings using compassion and introducing positive thoughts to neutralize harmful moods and thoughts.

Mindfulness-based relapse prevention (MBRP) is a mindfulness-based aftercare approach for substance use disorders. Delivered in eight weekly, 2-hr group sessions, the MBRP curriculum integrates mindfulness practices with cognitive behavioral relapse prevention strategies to support recovery from substance use. In contrast to cognitive behavioral therapy, which seeks to help clients understand and reappraise their cravings and triggers for substances, MBRP focuses on awakening the senses and accepting cravings without reacting. The goal of MBRP is to slow down the *automatic* reaction process by pausing (taking a breath or two), observing the present moment (seeing the warning signs of relapse), and bringing attention to the array of choices (applying coping skills) that exist in every moment. The emphasis is on self-control and conscious choice-making. Instead of mindless reaction, the option exists in the present moment to respond by choosing what is beneficial, not detrimental, to well-being.

Research on Mindfulness-Based Therapy

Research based on community-based samples has found that interventions inclusive of mindfulness improve symptoms associated with chronic stress, anxiety, depression, and attention-deficit/hyperactivity disorder. Meta-reviews of MBSR have found improved affect states, coping abilities, states of mind, and less emotional distress. Mindfulness-based cognitive therapy and MBRP also have been found to be effective in reducing risk of relapse and recurrence. It is argued that people in a more mindful state are better able to regulate their responses to stress (negative moods or cravings) because of their enhanced emotional awareness, insight, acceptance, and ability to revise mood states. Neurological research also shows that mindfulness strengthens the neural pathways between the executive functioning part of the brain (the prefrontal cortex) and the motivation/emotional parts of the brain (the limbic system), which is associated with stress response, emotional states, and pain perception.

Research evidence on mindfulness in correctional settings, while in its infancy, is growing. A

recent meta-analysis of yoga and mindfulness meditation in prison found small improvements in psychological well-being and behavioral functioning among those who completed yoga or meditation programs. Programs of longer duration were found to yield slightly larger improvements in behavioral functioning. One large-scale study conducted between 1992 and 1996 found that MBSR participants showed significant pre-post reductions in hostility, increases in self-esteem, and improvements in mood disturbance. These findings are consistent with other studies of meditation-based interventions (e.g., MBRP, Vipassana meditation, Zen Buddhist meditation) conducted in correctional settings that show significant improvements in criminogenic variables including negative affect, substance use, anger, and self-esteem.

Mindfulness for Correctional Populations

Being incarcerated or under correctional supervision is stressful. Being under surveillance or living under the threat of harm exposes justice-involved people to internal and external stressors that trigger the body and mind to go into a state of alert. Building abilities to better self-regulate and manage stress is an intervention that would likely benefit people confined to correctional settings or returning to the community from prison with or without supervision. Mindfulness-based interventions have the potential to help incarcerated people cope with conditions inside prison or jail, manage the anxieties associated with incarceration and release, and recover from disability, disease, and psychological distress.

Prison Life Is Stressful

Meditation and yoga programming offer a way to help incarcerated people manage the stresses and strains of prison life. Prison systems or individual facilities can partner with a variety of volunteer groups to access books, CDs, and DVDs on yoga and meditation; to provide in-person and online training on yoga and meditation; and to provide guidance on developing and maintaining yoga and meditation activities. Two established groups are Prison Mindfulness Institute and Prison Yoga Project. Training on MBSR is also available

online (see Palouse Mindfulness and Center for Mindfulness websites) and through workshops.

Starting a mindfulness program inside prison requires minimal investment (the purchase or donation of meditation cushions and yoga mats), a physical location (perhaps in the chapel, school, or gymnasium), and a volunteer to lead the program (until peers are trained). Meditation programming should build the leadership capabilities of prison residents by training them in MBSR and yoga, with certification as the end goal. Adding a sangha, a meditation community, which meets regularly after completing the MBSR or similar meditation program, supports the maintenance of a meditation practice and builds a community of support to sustain the practice of mindfulness.

Promoting Recovery and Rehabilitation Are Goals of Correctional Settings

Prisons employ a variety of cognitive behavioral therapies for anger management, changing thinking styles, and drug treatment. The effectiveness of these programs could be enhanced by adding mindfulness-based programs, such as MBSR and MBRP, as an aftercare component. Relapse prevention, whether defined in terms of preventing the use of substances, violence, or deviance, is critical to rehabilitation and recovery. Teaching skills and attitudes that help residents respond to distressing triggers or symptoms through mindfulness practices is made easy by the availability of manualized interventions and professional training opportunities online and through workshops.

Reentering the Community After Prison Is a Chronic Stressor

Not being able to find or keep a job, stable housing, reunite with family and friends, and function in a fast-paced world, combined with the constant threat of returning to prison, can trigger relapse and elevate risks of returning to prison. Chronic stress also interacts with two factors associated with reoffending: self-regulation—the ability to consciously moderate one's behavior and emotions; and negative affect states—including anxiety, anger, and depression. Being able to regulate thoughts, emotions, and actions translates into an ability to respond more judiciously to people, places, and things.

Mindfulness-based approaches have great potential as a reentry resource. By teaching people how to identify stressors, apply acceptance-based practices, and respond mindfully (not impulsively), mindfulness provides tools for living prosocially and with less stress, while also reducing factors that increase the risk of recidivism. Maintaining a mindfulness practice, however, can be challenging once a person is in the community. As with any practice, reinforcement is needed. Technology-based (e.g., computers, web, mobile devices) interventions are now available to support the practice of mindfulness in the community. Because stress is experienced in real time, support is needed immediately. There are web-based MBSR practices (including guided meditations, calming music, reinforcing messages, and readings on mindfulness) available at no cost. Furthermore, mobile devices, such as smartphones, offer the opportunity to get support as stress happens. As of 2017, there were more than 700 mobile apps related to mindfulness available, with many offered free or for a small fee. These apps vary in functionality, with some offering guided meditations or calming music.

The application of mindfulness to correctional programming and reentry is gaining momentum but there is resistance. Cultures of conflict and hierarchy have not traditionally embraced practices that espouse cooperation, compassion, and equality, although the latter are more likely to promote safety and security. Yet with more experimentation and evidence supporting the effectiveness of mindfulness-based practices in correctional settings, acceptance is building and adoption is happening.

MINNESOTA SEX OFFENDER SCREENING TOOL–REVISED (MnSOST-R)

The MnSOST-R was one of the earliest validated, actuarial risk assessment tool for sexual offenders. This entry describes the development and validation of the MnSOST-R in the context of evolving

risk assessment strategies and methods, which are essential for effective decisions in the criminal justice system.

Risk Assessment With Sexual Offenders

Determinations of risk occur across the criminal justice system. From decisions for setting bail, to sentencing, to establishing custody level, to determining conditions of release—implicit or explicit judgments about risk must be made. This has been true throughout modern correctional history.

Sexual offenders present even more challenges to the legal system because of additional risk assessment to inform additional high-stakes decisions unique to them. These include registration, community notification, and civil commitment.

In 1994, the U.S. Congress passed the Jacob Wetterling Crimes Against Children's Act, which required states to set up sexual offender registries in order to better track sexual offenders. Megan's Law, which took just 2 days to pass through the U.S. Congress in 1996 as an amendment to the Jacob Wetterling Act, authorized law enforcement agencies to notify the public about convicted sex offenders living, working, or visiting in their communities. It also required all states to develop a procedure for notifying the public when a convicted sex offender is released into their community.

To address these statutes, many states incorporated a three-tier system of risk (low, medium, or high) rather than identifying the specific types of offenders that are to be subject to notification. In Minnesota, for example, the Community Notification Act of 1996 called for a risk assessment scale to be implemented by January 1, 1997, and identified a series of factors to be used in assessing risk and assigning risk levels. As in many other states, those sex offenders determined to present the greatest risk received the highest level of community notification as well as supervision.

Also in the 1990s, states began to implement existing, or passed new, civil commitment statutes, often referred to as *sexually violent predator laws*. These statutes enabled states to commit the most dangerous sexual offenders to forensic hospitals rather than release them back into the community.

The policy justification for registration, community notification, and civil commitment statutes was protection of the public from the most dangerous sexual offenders. Clearly, then, the assessment and prediction of dangerousness is essential for the constitutional and effective implementation of these statutes.

While accurate assessment has always been important, the high-stakes decisions regarding sexual offenders helped focus attention on the objectivity, consistency, and accuracy of existing methods of risk assessment. The practice of sexual offender assessments in the 1980s and early 1990s was largely clinical and subjective in nature because of the standards of practice at that time and the absence of research on empirically validated risk indicators.

However, a compendium of studies, particularly in the 1980s, demonstrated that the clinical prediction of any type of longer term violence, including sexual violence, was essentially no better than chance. Consequently, reliance on clinical judgment alone resulted in numerous inaccurate predictions of sexual recidivism. On one hand, *false-positive* offenders were unnecessarily deprived of liberty, and the incorrect placement of offenders in prolonged and expensive treatment facilities put a great financial burden on the state. On the other hand, *false-negative* predictions risked placing dangerous sexual offenders in the community without appropriate supervision. There was a clear and compelling need for more accurate forms of risk assessment.

Since the 1950s, a growing body of evidence indicated that fully empirical approaches to diagnosis and prediction of future behavior outperformed clinical judgment. Such instruments included only variables that were linked to the target behavior by sound research, and each of these variables was assigned a relative weight empirically based on the strength of its relationship with the target behavior. This approach to assessment is now widely referred to as *actuarial assessment*.

By the early 1990s, several actuarial risk assessment tools had already established moderate predictive accuracy with general criminal recidivism (future commission of any criminal offense). However, those instruments were generally less successful at predicting violent recidivism,

including sexually violent recidivism. Clearly, a different set of variables were needed for the actuarial assessment of risk of sexual recidivism.

Minnesota Sex Offender Screening Tool

Doug Epperson, Jim Kaul, Steve Huot, and Robin Goldman began development of MnSOST in response to a 1991 Minnesota Department of Corrections special report calling for a more formal and uniform process to identify predatory and violent sex offenders. Few prediction models existed at that time, and many of those were dependent on clinical and/or phallometric data. A major limitation of such models is the fact that many sex offenders are not offered or refuse treatment and/or phallometric assessment, making clinical and phallometric data unavailable. From the outset, then, the goal was to create a reliable and valid predictive instrument that could be easily scored by correctional case managers using only information routinely available in correctional records.

Based on an extensive review of the relevant literature, an initial inventory of 14 items was developed. Although the items were empirically selected, the weights assigned to each item on this initial tool, the MnSOST, were based on clinical judgment. The initial MnSOST, thus, represented a structured clinical judgment approach to risk assessment in that it included only items with an empirical relationship to sexual recidivism but still involved a degree of clinical judgment. Results of two preliminary studies indicated that the MnSOST had acceptable reliability and modest predictive accuracy, demonstrating value to taking a more empirically structured approach to clinical judgment.

A major revision of the MnSOST was initiated in 1996. This was based on updated review of the literature to identify additional potential predictor variables and a commitment to making the revised tool a fully actuarial one in which both item selection and item scoring/weighting was empirically determined.

Minnesota Sex Offender Screening Tool–Revised

Development

Analyses to select and weight items for the MnSOST-R were performed on case files from

256 incarcerated sexual offenders in Minnesota from three cohorts: a random subsample of sex offenders released in 1988 ($n = 107$), a random subsample of sex offenders released in 1990 ($n = 107$), and a subsample of offenders readmitted to the Minnesota Department of Corrections for any reason during the time the sample was being put together, regardless of release year ($n = 42$). Most of the people in the last subsample were sexual recidivists ($n = 32$). This group was deliberately oversampled to provide more stability to any observed relationships between sexual recidivism and potential predictor variables.

The sample included sex offenders with a history of extrafamilial child molestation or rape of unrelated victims. For the purposes of this research, offenses involving vaginal or anal penetration of a victim aged 13 or younger were classified as rape. Forcible penetration was required for offenses against older victims to be classified as rape. Thus, the only group of sexual offenders excluded from the sample was those with an *exclusive* history of intrafamilial offenses that would *not* be classified as rape using the aforementioned criteria. This group was excluded because preliminary analyses indicated that this group was substantially different from the other groups on multiple dimensions.

Sexual offenders in the sample ranged in age from 17 to 70 years (mean = 32.42), and the ethnic mix of the sample was 66% European American, 23% African American, 5% Hispanic, 4% Native American, 2% other minority groups. On average, offenders in the sample had 0.82 *prior* sex convictions, with a range from 0 to 8.

To ensure that the tool could be used with a wide range of male sexual offenders, only variables that would be routinely documented in correctional case file were considered as potential items on the tool (predictors of sexual recidivism). The criterion variable, sexual recidivism, was defined as a formal charge for a new sexual offense within 6 years of release from prison.

Complex analyses identified 16 items that each made a unique contribution to the prediction of sexual recidivism (maximum identification of recidivists and nonrecidivists based on MnSOST-R total scores). With these 16 items in the predictive model, no other items significantly added to the prediction of sexual recidivism. Twelve of the

items were historical/static in nature, meaning that a score could only increase with time and not decrease. For example, once a person had one conviction for a sexual offense, the person could never have fewer in the future. However, future convictions for sexual offenses could add to that score. The historical/static items were number of convictions for sexual offenses, length of sexual offending history, commission of a sexual offense while under court supervision, commission of a sexual offense in a public place, use or threat of force in any sexual offense, perpetration of multiple sex acts in a single event contact, offending against victims from multiple age groups, offending against a 13- to 15-year-old victim with more than a 5-year age difference between the offender and the victim, victimization of a stranger in a sexual offense, persistent pattern of adolescent antisocial behavior, recent pattern of substantial substance abuse, and recent employment history. The remaining four items were institutional/dynamic items, meaning that they were reset to 0 at the beginning of any new incarceration for a sexual offense. These variables included discipline history, chemical dependency treatment recommendations and outcomes, sex offender treatment recommendations and outcomes, and age of the offender at the time of release from prison.

The MnSOST-R demonstrated good overall accuracy within the development sample. The most common statistic used to reflect overall accuracy of a risk assessment tool is the area under the receiver operating characteristics curve (AUC). An AUC value of .50 reflects chance levels of overall predictive accuracy, so a risk assessment tool must demonstrate an AUC value that is significantly greater than .50 using conventional statistical standards. In the development sample, the AUC was .77, significantly greater than chance. Furthermore, the tool performed equally well for various subgroups of offenders (rapists vs. child molesters and minorities vs. nonminorities).

Reliability

At least seven studies have assessed the reliability of MnSOST-R scores (agreement between raters on the scores of sexual offenders). Reliability coefficients can range from 0 (no reliability) to

1.00 (perfect reliability). The overall average reliability coefficient was .81. Five of the seven studies yielded reliability coefficients of .80 or higher, and the other studies produced coefficients of .68 and .76. There was minimal training of scorers in the latter two studies. Collectively, these studies demonstrated that, with modest training (a 1-day workshop), the MnSOST-R can be scored reliably.

Predictive Accuracy

Cross-validation studies are essential to demonstrate the predictive accuracy of the MnSOST-R with samples other than the development sample. In nine of 11 such studies, the predictive accuracy of the MnSOST-R was significantly greater than chance. The median AUC value across all 11 studies was .70, which reflects a moderate to high level of predictive accuracy.

The Current Context

The MnSOST-R always compared very favorably in reliability and predictive accuracy to other contemporary actuarial risk assessment tools for sexual offenders. In fact, the MnSOST-R and the Static-99 (and later the Static-99R), developed by Robert Karl Hanson and David Thornton, were the two most widely used tools of their type for about a decade in the United States. The latter tool was largely developed in Canada, which has a national tracking system for sexual offenders, making outcomes easier to determine. Because of this, the Static-99R established the most robust research base of all similar tools and is now the most widely used risk assessment tool for sexual offenders. Although the MnSOST-R was a pivotal tool in the transition to actuarial risk assessment, it is no longer supported by its authors. Anyone still using the MnSOST-R is encouraged to switch to the Static-99R.

MINOR CRIMINAL RISK FACTORS

Minor criminal risk factors are a broad set of individual and environmental characteristics. Compared to moderate and major risk factors (identified later in this entry), minor risk factors have a weaker association with criminal behavior. Examples of minor criminal risk factors include family structure, race/ethnicity, and socioeconomic status. Also included are mental health disorders, cognitive challenges, and community demographics. Despite their low predictive ability, minor risk factors are often the focus of crime research, crime prevention efforts, and offender treatment programs. This is because minor risk factors are theory-driven and retain the potential to contribute to criminal behavior. This entry focuses on minor criminal risk factors in the context of the Risk-Need-Responsivity (RNR) model. Theoretical origins of common minor risk factors and two important roles they have in reducing criminal behavior are highlighted.

RNR

A major approach to offender rehabilitation today is based on the three principles underlying the RNR model. The *risk principle* posits that an offender's level of risk of criminal behavior can be measured and that offender treatment services should be proportional to this risk level. The *needs principle* recommends this treatment be focused on addressing risk factors (termed

criminogenic needs) that are directly related to recidivism (e.g., antisocial cognitions and substance abuse). The *responsivity principle* has two main categories: general and specific responsivity. General responsivity refers to the use of programming that has been shown to be effective at addressing antisocial thinking and behaviors. This has typically been assumed to be cognitive behavioral programs. Specific responsivity pertains to individual characteristics and circumstances that impact engagement in and the effectiveness of treatment aimed at reducing criminal risk. General responsivity suggests an overall method for delivery of risk reduction efforts. Specific responsivity is necessary to tailor those efforts to an individual's abilities and resources.

Minor, Moderate, and Major Risk Factors

In 1994, Don A. Andrews and James Bonta introduced a theory of criminal behavior that focused on social learning. It would evolve into what is now known as the *General Personality and Cognitive Social Learning* perspective of criminal conduct. The General Personality and Cognitive Social Learning encompasses the RNR model. Supported through extensive research, the General Personality and Cognitive Social Learning categorized criminal risk factors as minor, moderate, and major. Research has identified a set of *big four* risk factors that predict criminal involvement most reliably. These major risk factors are antisocial personality patterns, criminal history, antisocial attitudes and cognitions, and antisocial associates. The four moderate risk factors have weaker associations with criminal behavior than the big four. They include low levels of performance and satisfaction in education and/or employment, lack of family and marital supports, substance abuse, and lack of involvement in prosocial leisure activities. The four major criminal factors combine with the four moderate risk factors to form what is known as the *central eight* risk factors. Minor risk factors represent a set of attributes that are not specifically defined aside from their relatively low association with criminal behavior and their shared history of being identified as contributors to crime.

Origins of Minor Risk Factors

Theories to explain crime and criminal behavior have identified a wide variety of criminal risk factors. This section focuses on theories in criminology that aim to identify objective and measurable predictors of criminal behavior. These theories can be categorized based on whether biological, psychological, or social structures and processes are proposed to determine an individual's involvement in crime.

Early biological theories of criminal behavior focused on outward physical traits and appearances (e.g., physical abnormalities and body type, skull shape, skin color). Later biological approaches have attempted to identify heredity and genetic characteristics that predict crime. Early biological theories have largely been discredited. However, the principal that structure influences function remains at the heart of modern neurobiological approaches exploring the role that biology plays in producing criminal behavior.

Serious mental illnesses and low intelligence have been explored as predictors of criminal behavior. This research has been justified largely upon the observation that people with these conditions are overrepresented in jails and prisons. However, studies testing the relationships among these mental characteristics and crime have shown them to have poor predictive ability relative to the moderate and major risk factors identified in the previous section.

Control theories of criminal behavior focus on socialization processes that promote ties to social norms unsupportive of crime. Psychoanalytic theory emphasizes the role of the family in promoting socialization. It directed research to focus on the roles family structure (e.g., single vs. dual parenting), familial patterns of crime, and family cohesiveness play in crime. Social bond theory of crime broadens the focus from bonding with the family to an individual's bond with society. Social bond theory centers on an individual's involvement with prosocial activities and one's belief in the value of a conventional moral order.

Elements of these theories have appeared as major and moderate risk factors. For example, a lack of nurturing and caring family and marital supports (a moderate risk factor) reflects psychoanalytic theory's focus on the role of the family.

Antisocial cognitions and attitudes (a major risk factor) reflect the value and belief in moral order component of social bond theory. However, due to a lack of strong evidence of their direct relationship with crime, family structural features have been referred to the category of minor risk factors.

Looking more toward social-structural determinates of criminal behavior, sociologists have posited several criminal risk factors. For example, anomie theory suggests that unclear social standards and a lack of social controls lead to individual feelings of isolation (a minor risk factor) and criminal behavior. Strain theory suggests emotional distress (a minor risk factor) that arises from one's desire to attain culturally defined goods along with barriers to lawful methods for attaining those goods (e.g., poor educational and employment opportunities) can lead to criminal involvement.

Social disorganization theory and broader ecological perspectives suggest that low income, highly mobile, and ethnically diverse neighborhoods hinder the development of a shared prosocial value system. Such neighborhoods are also suggested to lack the formal and informal social controls to promote adherence to this value system. As a result, lower class origins have been identified as a criminal risk factor. Again, relative to major and moderate risk factors, measures of anomie, emotional distress, and low social class origin have less ability to predict criminal behavior.

Minor Risk Factors as Indirect Risk or Responsivity Factors

So the question then is why consider minor risk factors at all if they have weak relationships with criminal behavior? The answer is that these risk factors have an important role to play in crime prevention efforts. Two examples of this role are provided here: (1) as indirect, *upstream* targets for crime prevention and (2) as characteristics of offenders and their environments that should be considered to improve engagement in treatment.

Several of the minor risk factors identified in this entry are weak indicators of criminal risk due to being relatively removed from actual criminal

behavior. That is, their relationship with crime is often realized through major and moderate risk factors. Community-level risk factors highlight this point. For example, research has shown that the strength of the direct relationships among neighborhood characteristics (e.g., minor risk factors of neighborhood crime, disadvantage, and low socioeconomic status) and crime is reduced when considering family characteristics (i.e., the moderate risk factor of parental caring and monitoring) and personal risk levels of residents (i.e., the moderate risk factor for lack of attachment to school/work and the major risk factor for antisocial associates).

The role major mental illnesses play in crime provides another example of minor risk factors having a less direct (and thus weaker) relationship with crime than moderate and major risk factors. Research has shown that mental illness (a minor risk factor) increases the odds of a person being unemployed, engaging in substance use, possessing antisocial personality patterns, and having antisocial associates and friends. These are all either moderate or major risk factors that have strong associations with criminal behavior and, as such, may put some people with mental health problems at increased risk of engagement in crime.

Finally, barriers to conventional methods of obtaining valued goods (a minor risk factor identified from strain theory) can result in low levels of performance in school and/or work, thus increasing an individual's risk for criminal involvement. These relationships point to important criminal precursors that can serve as targets for crime prevention efforts. For example, mental health treatment and supported employment services may prevent crime by increasing employment. Mentoring programs may help to reduce criminal risk by providing prosocial role models and associates in communities where these are lacking.

In addition to having a role in crime prevention, several minor risk factors should be considered in the delivery of services aimed at reducing the negative impact of moderate and major risk factors. That is, some minor risk factors may be more appropriately considered under the rubric of specific responsivity in the RNR model. For example, anxiety, low self-esteem, and serious mental

illness may impact delivery of cognitive behavioral programs aimed at reducing antisocial cognitions. Individual treatment and programming that moves at a slower pace may be more effective than traditional group-based programming when these conditions are present.

Community characteristics such as availability of services and safety accessing services are minor risk factors identified from social disorganization theory. However, these factors need to be taken into consideration when attempting to engage people in community-based programming that targets criminal risk factors. Similarly, serious offending and low spirituality among offenders (both minor risk factors) may impact access to and engagement in programming. Those with serious criminal histories may be restricted from certain service settings. Those who do not consider themselves spiritual should not be expected to participate in faith-based programming. Thus, minor risk factors can play a substantial role in an individual's response to treatment programs, ultimately influencing outcomes related to criminal risk.

Space limitations do not allow for the identification of the full potential minor risk factors have for contributing to criminal behavior. However, their theoretical underpinnings, along with their potential to function as crime prevention targets and as responsivity factors, indicate that minor risk factors should not be dismissed as unimportant. Indeed, the use of the term *minor* may be a bit of a misnomer. The concepts that constitute minor risk factors play important roles in criminal involvement and have implications for how treatment for major and moderate criminal risk factors can be most effectively employed.

MIRANDA V. ARIZONA (1966)

Miranda v. Arizona was a landmark case decided by the Supreme Court of the United States in 1966, in which the Court articulated the idea of “*Miranda* warnings.” In brief, the *Miranda* decision held that suspects questioned by police must be informed of certain rights; otherwise, any statements the suspects make will not be admissible in court. Although the *Miranda* rights are unquestionably important, suspects can—and often do—give them up (i.e., waive their rights) and talk with police. Thus, the underlying issue in cases involving *Miranda* warnings is whether the waiver was valid and whether the suspect's statements (e.g., a

confession) are therefore admissible. In some cases, forensic psychologists are brought in to help the court determine waiver validity by evaluating a suspect's ability to waive the *Miranda* rights. This entry focuses on the law surrounding *Miranda* warnings and waivers, and the role of psychologists in conducting research on and evaluations of *Miranda* warnings and waivers.

Miranda Warnings

The Supreme Court's decision in *Miranda v. Arizona* was based on the Fifth Amendment to the U.S. Constitution's protection against self-incrimination—the right not to be forced to make incriminating statements against oneself. The decision resolved four consolidated criminal appeals; in each case, the defendant had been questioned at length by police without being satisfactorily notified of his right to remain silent or his right to a lawyer. The Court held that custodial interrogations by police are inherently coercive, and therefore, police must take certain steps to protect suspects. Specifically, suspects should be told of their rights so that they can make an informed decision about whether to exercise or waive them. The Court therefore recommended a set of warnings informing the suspect of (a) the right to remain silent, (b) use of the suspect's statements against him or her at trial, (c) the right to a lawyer, and (d) the right to an appointed lawyer for indigent suspects. The Court also stated that suspects can invoke these rights at any point during an interrogation, though it did not specify whether police needed to inform suspects about the continuing nature of their rights. One year after *Miranda*, the Court extended the same rights to juvenile suspects with *In re Gault*. Although the Court specified the content of the warnings, as described earlier, it has taken a flexible approach with respect to the specific language used to communicate the warnings. Therefore, hundreds of different versions of the *Miranda* warnings are used across the country.

Two nuances are essential to appreciate how *Miranda* applies to the day-to-day practice of police work. First, *Miranda* did not establish a procedural rule that police are required to follow; rather, it created a rule of admissibility in court: A defendant's statements cannot be admitted into evidence against him or her if he or she was not informed of her

rights. Second, *Miranda* does not apply to every interaction between citizens and police; it only applies to *custodial interrogations*. In subsequent cases, *custody* was defined as whether, given the circumstances of the interrogation, a reasonable person would feel free to leave. *Interrogation* refers to both direct questioning and other comments or actions by police that are reasonably likely to elicit incriminating information from a suspect.

Miranda Waivers

In addition to describing the components of the *Miranda* warnings, the Court also identified the requirements for a valid *Miranda* waiver. *Miranda* waivers must be *knowing*, *intelligent*, and *voluntary*. Broadly speaking, the knowing and intelligent elements refer to a suspect's comprehension of the warnings; voluntariness requires that the waiver was made without police coercion. Therefore, to execute a valid waiver, suspects must have understood the meaning of the warnings and the implications of giving up their rights, and they must have made the decision to waive their rights free from pressure by the police.

Courts determine the validity of *Miranda* waivers using the *totality of the circumstances* approach. This approach, which courts use to evaluate several different types of legal questions, directs courts to examine *all* of the factors relevant to a given issue. For *Miranda* waivers, there are two broad categories of factors: those related to the interrogation and those related to the suspect. Interrogation-specific factors can include the length and timing of the interrogation, the number of officers present, and interrogation methods. Thus, lengthy interrogations that take place overnight, include several officers in the interrogation room, or employ psychologically coercive interrogation strategies could lead a court to find a waiver invalid. Suspect-specific factors often include age, intelligence, comprehension of rights, and prior experience with the justice system. Thus, a *Miranda* waiver by a young suspect with low intelligence and no prior experience with police will more likely be deemed invalid than a waiver by an older suspect of average intelligence and a history of arrests. However, courts are free to consider other factors they find relevant, and each analysis is individualized to the case at hand.

Miranda Research

Miranda research largely consists of studies evaluating how well people comprehend the *Miranda* rights, how people make the decision to waive or invoke their rights, and the *Miranda* warnings themselves. Much of the seminal research on comprehension of *Miranda* rights was conducted by Thomas Grisso. Key among his contributions in this area was the translation of the legal terms *knowing* and *intelligent* into the psychological terms *understanding* and *appreciation*, respectively. Understanding encompasses one's basic grasp of the *Miranda* rights' meaning, and appreciation refers to one's ability to apply the rights to his or her situation and recognize the consequences of waiving or asserting the rights. With the concepts thus defined, Grisso established a set of instruments, the Instruments for Assessing Understanding and Appreciation of *Miranda* Rights, which allow reliable measurement of *Miranda* comprehension.

Over several decades of research, age and intelligence have consistently emerged as the factors most strongly associated with *Miranda* comprehension. Generally, youth under the age of 12 years rarely demonstrate adequate understanding of the *Miranda* rights, whereas youth in middle adolescence (i.e., ages 13–15) demonstrate variable understanding. Older adolescents' *Miranda* comprehension more closely resembles that of adults, though age and intelligence together are better predictors than age alone among adolescents. Differences among adults are primarily due to differences in intelligence as opposed to differences in age. Not surprisingly, intelligence generally, and verbal intelligence specifically, is often correlated with *Miranda* comprehension among youth and adults. Finally, individuals with more severe intellectual impairments (e.g., intellectual disability) consistently demonstrate inadequate *Miranda* comprehension.

Academic achievement, particularly reading and listening comprehension, has also been found to predict *Miranda* comprehension in some studies. Although the results of studies evaluating the relationship between academic achievement and *Miranda* comprehension are more mixed, the inconsistent findings may be partially attributable to the wide variety of *Miranda* warnings described

further later in this section. Researchers have also investigated the relationship between the presence of mental illness and *Miranda* comprehension. Generally, results of these studies indicate that the presence of psychotic symptoms and other symptoms of severe mental illness associated with inpatient hospitalization are related to *Miranda* comprehension, whereas symptoms of depression and anxiety are not. Finally, although courts often rely on experience with the justice system as an indicator of a particular defendant's *Miranda* comprehension, research consistently indicates that prior justice system experience does not predict understanding or appreciation of the *Miranda* warnings.

Miranda researchers have also investigated the factors associated with decisions to waive the *Miranda* rights. Although the rates of *Miranda* waivers are difficult to estimate, research suggests that a high percentage of suspects—roughly 80% of adults and 90% of youth—do waive their rights. Overall, research indicates an inverse relationship between *Miranda* comprehension and waiver decisions. That is, an individual with lower *Miranda* comprehension is more likely to waive his rights, and vice versa. Furthermore, individuals less able to consider long-term consequences are more likely to waive their rights to avoid the negative immediate consequences of invoking their rights (e.g., stress associated with asserting oneself to police).

Finally, regarding the *Miranda* warnings themselves, researchers have found hundreds of different versions of the warnings with dramatic differences in their length and comprehensibility. For example, the reading comprehension levels of *Miranda* warnings can vary from approximately third grade to the postgraduate level. Existing research also suggests that there is variability among jurisdictions with respect to how the warnings are administered (i.e., oral, written, or both), though most officers report administering the warnings orally.

Forensic Evaluations of *Miranda* Waivers

Forensic mental health professionals are sometimes asked to evaluate a defendant's ability to waive the *Miranda* rights. These professionals can be forensic psychologists, psychiatrists, and

on occasion social workers, but the term *forensic psychologist* is used for this entry. Although judges make the final determination on the waiver's validity, forensic psychologists can inform courts about relevant totality of the circumstances factors, particularly a defendant's understanding and appreciation of *Miranda* rights.

Typically, forensic psychologists receive referrals for evaluations of *Miranda* waivers from defense attorneys who are attempting to exclude their clients' incriminating statements from trial. The forensic psychologist will review relevant records, including third-party or collateral information (i.e., information that does not come directly from the subject of the evaluation). This allows the psychologist to corroborate information provided by the defendant, which is particularly important in the context of forensic mental health assessment when the defendant may be motivated to distort facts or conceal information unhelpful to the case. For instance, consider a defendant who shows very poor understanding of the *Miranda* rights and scores low on an intelligence test administered during the evaluation. The forensic psychologist would likely reach different conclusions if the defendant had a history of special education or documented intellectual disability than if he had a history of high academic achievement and successful employment in a competitive field. In the context of *Miranda* evaluations, relevant records include school, employment, mental health, and medical records. Whenever possible, forensic psychologists will also review the *Miranda* waiver form the defendant signed and any audio or video recording of the interrogation.

The next step in the *Miranda* evaluation will be an interview with the defendant. The first part of the interview usually entails a thorough biopsychosocial history (an interview of an individual's biological, psychological, and social history). Then the psychologist will ask for the defendant's account of the arrest, interrogation, and administration of the *Miranda* warnings. If the psychologist was able to obtain the defendant's actual waiver form or a printed version of the *Miranda* warnings used in that jurisdiction, he will then ask the defendant to read each right aloud and paraphrase it.

Many forensic mental health assessments include psychological testing, and evaluations of *Miranda* waivers are no different. Depending on the case, the forensic psychologist may determine that intelligence or academic achievement testing is necessary. For defendants with a history of psychiatric conditions or treatment, broad personality testing or specific symptom inventories may be useful. Finally, there are specialized forensic assessment instruments specifically designed to provide information about an evaluatee's understanding and appreciation of *Miranda* rights: the *Miranda* Rights Comprehension Instruments, an updated version of Grisso's instruments, and the Standardized Assessment of *Miranda* Abilities. Although differences exist between these sets of instruments, both assess individuals' abilities to put the *Miranda* warnings in their own words, define *Miranda* vocabulary terms, and appreciate the significance of waiving their rights.

Finally, the forensic psychologist will synthesize the information obtained into a report. As referenced earlier, the report will not address the validity of the waiver but rather the capacity of the defendant to provide a knowing, intelligent, and voluntary waiver of *Miranda* rights.

MITIGATION

In the U.S. legal system, mitigation (known also as *mitigating evidence* or *mitigating factors*) encompasses facts about a defendant's background, character, and the circumstances of the offense. While not introduced to lessen legal culpability, mitigating factors may lessen a defendant's moral culpability. Thus, mitigation is not introduced to absolve guilt but rather to lessen a sentence or judgment by contextualizing the defendant's behavior. Although sometimes observed in civil cases and criminal sentencing generally, the majority of mitigation is presented by criminal defense in capital (i.e., death penalty) cases. This entry describes the legal roots, definition, and practice of mitigation, concluding with a discussion of research on mitigation in capital jury decision-making.

Legal Roots and Definition of Capital Mitigation

In 1972, the U.S. Supreme Court ruled in *Furman v. Georgia* (1972), that the death penalty had been arbitrarily and capriciously applied and was thus unconstitutional under the Eighth Amendment to the U.S. Constitution's ban on cruel and unusual punishment. The Congress and 35 states responded by rewriting capital punishment statutes, and in 1976, the Court ruled that certain new frameworks satisfied the Constitution, effectively lifting a 4-year moratorium on death sentences in the United States. Frameworks passing constitutional muster provided objective criteria directing and limiting death sentences, ensured appellate review, and permitted the sentence to take into account the defendant's character and record. Today, although nuanced differences exist among the states, three features relevant to mitigation are common: (1) capital trials are bifurcated, with separate guilt and penalty phases heard by the same jury; (2) the jury is allowed to consider evidence of aggravating and mitigating factors during the penalty phase; and (3) jury instructions must provide guidance to juries making life-versus-death recommendations.

Subsequent rulings have further refined capital jurisprudence, including that juveniles and individuals with intellectual disability are ineligible for death and that only murder may be punished by death. Prosecutors must also prove the existence of at least one aggravating factor for a defendant to be eligible for death. While aggravating factors vary by state, they must be statutorily defined and thus generally refer to characteristics of the murder itself. Common aggravators include murder committed for pecuniary gain, murder of a law enforcement officer, and murder perceived as especially heinous, atrocious, and cruel.

If aggravating evidence is presented, then the defense presents mitigation. Some mitigators are prescribed by statute, while others are nonstatutory and unlimited in content. Mitigation can be separated into two broad categories: *proximal mitigation*, which is directly connected to the offense, and *remote mitigation*, which is unrelated to the offense but relevant to the defendant's life history. Commonly presented mitigators reflect childhood trauma, mental illness, and

unlikelihood of future violent behavior. While aggravators must be proven beyond a reasonable doubt, mitigating factors require proof by a preponderance of the evidence.

Since the death penalty was reinstated, the Court has also clarified the defense's duty to investigate and present mitigation in capital cases. It has ruled that juries must consider any potential mitigation and must assign it some weight in decision-making. While the value of mitigating factors is individually evaluated by each juror, the final sentencing recommendation must be unanimous based on a weighing or balancing of the aggravating and mitigating evidence.

The Practice of Capital Mitigation

The American Bar Association has long recognized that capital defense is unique and requires specialized training but only recently has it acknowledged that attorneys lack the skills and knowledge to conduct a mitigation investigation. In the early 2000s, the role of the mitigation specialist was formally established by the American Bar Association, which later published supplementary guidelines on the mitigation function of defense teams in capital cases. These guidelines require the capital defense team to be composed of two defense attorneys, a guilt-phase investigator and a mitigation specialist.

Mitigation investigation is a form of forensic assessment that focuses on the identification and presentation of mitigating factors unique to each capital defendant. Mitigation is considered a fact-based form of investigation, the reliability of which must be established using a cross section of data from multiple sources. Toward that end, the mitigation specialist must collect and analyze records on the defendant then conduct interviews with the defendant, the defendant's family, and any individuals (e.g., teachers, employers, friends) who may have known the defendant well. The end product of a mitigation investigation includes an extensive social history and a chronology of significant life events, often provided to mental health experts who may testify in the sentencing phase.

Qualifications for mitigation specialists vary by state, but most are trained in forensic social work and related mental health professions. Few states

require a specific educational degree, but all require experience and apprenticeships in capital mitigation. Although psychologists and psychiatrists have the prerequisite knowledge of human behavior, many lack training in investigation, which is usually conducted outside of an office setting. A notable weakness of mitigation training is that it is usually offered by attorney-based organizations, which may not be well-grounded in the psychological sciences.

Research on Capital Mitigation

Research on capital mitigation and the penalty phase of capital trials generally has found that not all jurors are equally likely to sentence a defendant to death. All capital jurors must be *death-qualified* during jury selection, which means they must state a willingness to consider both life and death at sentencing. But, compared to their disqualified counterparts, death-qualified jurors are more likely to support the death penalty in general, and they tend to be more open to aggravating factors than mitigating evidence. Much research has focused on race, and indeed, White males as a group tend to be especially death-prone, particularly in cases involving Black defendants. By contrast, Black jurors are most receptive to mitigation, giving it greater weight in sentencing than White jurors. Victim race also plays a role with a death sentence being more likely when the victim is White.

One of the most robust findings about capital sentencing is that jurors often do not understand jury instructions about mitigation or aggravation, and they find it especially difficult to weigh them against each other. Worse yet for the convicted, when juror comprehension of instructions is low, jurors are more likely to give a death sentence.

MIXED SEXUAL OFFENDERS

Sex offenders are a diverse and heterogeneous group of offenders who differ in age, victim preferences, motivation, degree of planning, type of contact with the victim, and psychological issues that contribute to the commission of a sexual offense. Mixed sexual offenders refer to a subtype of sex offender who generally commit contact offenses (i.e., those involving physical contact with a nonconsenting person in a sexual manner) against adult and child victims. Thus, they may show little discrimination in the age of the victim and whether or not they have developed secondary sexual characteristics. The term *sexual polymorphism* or *victim crossover* has also been used to characterize this group of offenders, reflecting their tendency to switch among victim types.

Mixed sexual offenders have important similarities and differences from other types of contact and noncontact sex offenders such as rapists (i.e., men with adult, typically women, victims) and child molesters (i.e., men who exclusively sexually offend against underage children). The emphasis in this entry is on those differences that primarily pertain to psychological characteristics that have relevance to risk assessment (i.e., will they do it again?) and risk management (i.e., what can be done to prevent them from reoffending?).

Criminogenic Need Profiles

A large array of risk factors has been identified in the existing literature that predict future sexual violence among sex offenders, but two broad domains have special relevance: sexual deviance (e.g., unusual or atypical sexual interests, such as sex with children, evidence of a high-sex drive, and preoccupation with sex) and general criminality (e.g., broad issues that contribute to offending in general such as problems with aggression,

substance abuse, impulsivity, and antisocial personality features). These two broad domains not only predict sexual violence, but some scholars have argued that they may even have causal relevance in the origins and persistence of sexual offending, meaning they are criminogenic (i.e., crime causing). These areas are also stable and enduring but may have the potential to change gradually through treatment or other change agents in order to reduce the risk of sexual violence.

Research demonstrates that mixed sexual offenders can have high levels of sexual deviance, including interests in a range of deviant stimuli (e.g., children in addition to adults), issues with compulsive sexual behavior and problems with urge control, and lifestyle patterns that are conducive to sexual offending (e.g., developing relationships or routine activities that provide an opportunity to engage in deviant interests or to have contact with possible victims). Evidence from studies using penile plethysmography, in which penis erectile patterns are monitored in response to a range of stimuli, has demonstrated that mixed sexual offenders tend to demonstrate higher levels of arousal to images of children than offenders who have exclusively adult victims (i.e., rapists). Given that mixed sexual offenders by definition have multiple victims ranging from childhood to teen or adulthood, this pattern of findings makes sense clinically.

Second, mixed sexual offenders also tend to have pronounced issues in general criminality, including problems with nonsexual aggression (e.g., fighting, assaults), lifestyle impulsivity (e.g., instability in behavior, relationships, employment), substance abuse, and anger/hostility. Often, mixed sexual offenders will have many of the features of antisocial personality disorder, which involves a reckless disregard for societal norms, a persistent pattern of aggression or other forms of criminal activity, and impulsivity. The profile of general criminality characteristics is not unlike that of rapists or men in prison settings who commit nonsexual offenses (e.g., theft, assault, robbery), and usually mixed offenders will have a criminal record that includes both sexual and nonsexual crimes. Comparative examinations among offender subtypes have demonstrated that mixed offenders score similar to rapists on various

indicators of general criminality or antisociality and significantly higher than men who have exclusively child victims.

Psychopathy in Mixed Sexual Offenders: Profiles and Prevalence

Mixed sexual offenders are also more likely than other offender groups to display the features of psychopathy, a serious personality disorder that includes not only many of the behavioral features of antisocial personality disorder but also certain interpersonal and emotional characteristics such as a lack of guilt or remorse, lack of empathy, shallow emotions, failure to accept responsibility, deceitfulness, manipulation, and grandiosity. Research using a structured checklist to diagnose psychopathy, the Hare Psychopathy Checklist–Revised (PCL-R), shows that mixed sexual offenders tend to score substantially higher than child sexual offenders on the PCL-R and to demonstrate a profile more similar to that of rapists. Some of these lines of research have shown that while mixed offenders score similarly to rapists on the antisocial lifestyle features of psychopathy (what is known as *Factor 2*), they sometimes score higher on the interpersonal and emotional features of psychopathy (what is known as *Factor 1*) described previously.

Research examining profiles of psychopathy among sexual offenders featuring the PCL-R, in turn, have found that mixed sexual offenders frequently have the highest rates of being diagnosed as psychopathic. These studies have tended to use prison samples, and while the average rate of psychopathy tends to be about 15–20% in these samples and among sex offenders in general, the rate of psychopathy diagnosis among mixed offenders has ranged from 30% to as high as 60% across Canadian and U.S. samples.

Risk of Future Sexual Violence and Rates of Recidivism

Given that mixed sexual offenders tend to have pronounced concerns on both the sexual deviance and general criminality risk-need domains, including higher levels of psychopathy, naturally they also happen to be at higher risk of future sexual violence as well as other types of offending

compared to many other contact sex offender groups. Specifically, they are more likely to score high risk on structured risk assessment measures, including the Static-99, Rapid Risk Assessment for Sexual Offense Recidivism, Violence Risk Appraisal Guide, Sex Offender Risk Appraisal Guide, Minnesota Sex Offender Screening Tool, Sexual Violence Risk-20, and the Violence Risk Scale–Sexual Offender Version.

In addition to scoring higher on structured risk assessment measures, some studies have shown mixed sexual offenders to have higher rates of recidivism than other sex offender groups, although the results vary depending on the sample and setting. For instance, a large Canadian study published in 2014 conducted on a sample of over 2,000 incarcerated sexual offenders under jurisdiction from the Correctional Service of Canada (i.e., serving sentences of at least 2 years) tracked the reoffending patterns of these men who were followed up an average of 12 years after release. Overall, 12.6% of the sample were convicted for a new sexual offense while over 30% were convicted for a new violent (sexual or nonsexual) offense. Among the 275 mixed offenders included in this sample, roughly 15% were convicted for a new sex offense and 29% any new violent offense; these rates of reoffending were not significantly different from those found among rapists or child molesters. Elsewhere, however, at least two studies, published in 2006 and 2011, have reported rates of sexual recidivism among mixed offenders at approximately 40% with longer follow-ups (i.e., in excess of 10 years). Importantly, these samples were based in high-security forensic psychiatric settings, so it is likely that they were also at higher risk than the men in the large-scale federal cohort sex offender follow-up study.

In light of their profile of risk and needs, there are multiple considerations as to why mixed sexual offenders often have higher rates of sexual and violent offending outcomes compared to men with child victims exclusively or relative to nonsexual offenders in general. For one, the relatively high prevalence of psychopathy diagnoses compared to other offender groups, and by extension, high PCL-R scores, indicates that mixed sexual offenders are criminally versatile. That is, they are likely to commit varied offenses whether these be sexual or nonsexual in nature, and this may partly

account for why mixed sexual offenders sexually victimize both children and adults. It is also likely that sexual deviance (i.e., unusual and varied sexual interests, such as attraction to children) plays an important part in offending, given that mixed sexual offenders also tend to have significant concerns in this area. In addition, the fact that the majority of psychopathic offenders do not sexually victimize children would seem to further speak to the role of sexual deviance in sexual offending among mixed sexual offenders.

The victim crossover literature comparing mixed sexual offenders to child molesters and rapists also identifies important similarities and differences that have risk implications. A 2012 study examining the offense narratives and motivations of sex offender subtypes found that mixed sexual offenders had a greater degree of versatility in the crimes they committed. For example, they may vary the amount of planning, control the victim or situation, or use force depending on the circumstances of the situation and the characteristics of the victim. This so-called target switching has been suggested to be attributable to a high degree of sexualization (i.e., desire for sexual contact regardless of the target), one aspect of the broader sexual deviance construct. This versatility in planning also likely translates into mixed sexual offenders being able to successfully complete attempted sexual assaults more frequently than other sex offender subtypes.

Response to Treatment and Risk Management

The limited research available has demonstrated that mixed sexual offenders are no less likely to fail to complete sexual offender-specific treatment or to derive any fewer benefits from treatment than other sex offender groups. For instance, a 2007 Canadian study of treated incarcerated sex offenders found that mixed sexual offenders demonstrated the same degree of treatment gain in terms of how much their risk was reduced compared to other sex offenders. As mixed sexual offenders tend to have a larger number of treatment targets and often higher rates of recidivism postrelease, this would further necessitate a comprehensive program to manage the many needs of this complex offender group, particularly in the domains of sexual deviance and general criminality.

Given the relatively high prevalence of psychopathic personality among mixed sexual offenders, treatment programs would also need to be alert to behaviors that interfere with treatment that could increase risk of dropout (e.g., disruptive behavior, poor motivation, manipulation, lack of readiness to change) in order to retain this clientele so that they may potentially benefit from treatment.

Conclusion

Mixed sexual offenders are a complex multineed group of offenders, who tend to be higher risk, more psychopathic, and often have higher rates of sexual and other forms of reoffending than other sex offender groups. The victim crossover literature, in turn, identifies this group of offenders broadly as having the greatest offense versatility in their capacity to plan and complete sexual offenses. This mode of planning, coupled with their profile of risk and needs and their potential to respond to treatment, all emphasize the importance of intensive treatment and reintegration efforts to prevent sexual victimization and promote public safety.

MOTIVATION TO CHANGE

The motivations behind thought and behavior change are subjective and enigmatic: That which impels one person to act may have no effect on another. Confounding the challenge of identifying motivation is the fact that the mechanisms of action for each individual can be greatly influenced by factors such as time and environment. The particularity of motivation has made the psychology of change a critical area of interest for practitioners and researchers across a range of professions and academic disciplines. By gaining a deeper understanding of how and why people choose to change, practitioners and researchers can develop tools, programs, and interventions that effectively help populations eliminate or minimize unhealthy behaviors and/or adopt healthy ones.

Motivational interviewing (MI) is a notable tool that has emerged from this area of interest. This empathically collaborative counseling style aims to draw out the client's own motivation to change, moving the client away from feelings of ambivalence and closer to his or her desired goals. By harnessing the client's intrinsic motivation, as opposed to using extrinsic forces, the desire to change becomes a natural extension of the individual's process. This entry provides a brief overview of MI and discusses its applicability to the fields of criminal justice and criminal psychology.

Overview of MI

Clinical psychologist William R. Miller introduced MI in 1983. Through his work on the prevention and treatment of addiction, MI was developed as a tool to help clinicians work with individuals who expressed ambivalence about a proposed behavior change. The idea of ambivalence is key here, as MI is specifically focused on helping an individual move from a feeling of uncertainty to an organic decision about making a particular change in or choice about his or her life. Since its inception, MI has come to be utilized in a multitude of clinical settings not just its original application in addiction prevention and treatment. While MI is a complex style that must be learned and practiced over time, at its very core, it is

simply a way of being and conversing with people; this fundamental core is what many in the MI field call the style's inherent *spirit*.

Within therapeutic relationships, there is typically a complex dynamic present between the clinician and the client. Clinicians are often seen as (and can perceive themselves to be) experts or educators exerting power and knowledge onto their clients. MI seeks to diverge from this traditional approach, instead viewing therapeutic relationships as a collaborative partnership between the clinician and the client. The MI style requires the clinician or practitioner to level the playing field, so to speak, by entering the relationship as an equal partner and active listener who will work cooperatively with the client to elicit the client's naturally stated goals, as opposed to goals imposed by the practitioner. It is this person-centered, nonexpert-recipient foundation that sets MI apart from other counseling approaches. Building from this base, Miller and Stephen Rollnick identified four key processes that drive the MI approach: *engaging*, *focusing*, *evoking*, and *planning*.

Engaging refers to building rapport with the client. Arguably, the most critical element of a therapeutic alliance, as research has shown, is the quality of the relationship between the practitioner and the client. A strong working relationship between the two parties allows truthful thoughts and goals to be shared more freely and reinforces the foundation necessary for a fruitful therapeutic relationship.

Focusing is the process by which the practitioner gently directs the conversation and maintains its focus on the potential for change. This process keeps the discourse concentrated on the task at hand. By respectfully and skillfully avoiding repeated digressions, the practitioner leaves ample room for the client to explore the presenting issue and uncover thoughts, feelings, and motivations related to their desired change, perhaps for the first time.

Evoking, perhaps the most vital component to MI, refers to drawing out the client's inherent motivation to make a change in his or her life. This is done by:

- *asking open-ended questions*, which gives the client the opportunity and space to talk through his or her thoughts, feelings, and desires;

- *affirming*, or supporting and encouraging the client, not only when the client does something typically seen as positive but also supporting the client's autonomy and self-worth as a human being;
- *reflecting*, or the process of the practitioner hypothesizing what the client means by his or her expressions, both verbal and nonverbal. These guesses are offered back to the client in an effort to elicit a deeper, more insightful response;
- *summarizing*, which is reflecting back to the client a compilation of what the client has shared and expressed. Deciding which points to summarize is up to the practitioner, but the goal should always be to bring forth an accurate representation of what the client has discussed, providing the client with the opportunity to hear a translation of what he or she has expressed. Summarizing shows that the practitioner has been listening carefully to the client, reinforcing the rapport and partnership;
- *providing information/advice*, often prompted by summarizing, which—within the framework of MI—can only be done with the permission of the client. This is one area where MI greatly diverges from traditional therapeutic relationships whereby the practitioner enacts the role of expert and/or teacher. In the MI approach, there is still the belief that a skilled practitioner will have knowledge that, if shared, may help the client, but this information can only be transferred to the client with the client's consent. This process reinforces the equal partnership between the two parties and shows respect for the client's autonomy; and
- *planning*, which involves creating a specific roadmap for accomplishing the client's desired changes. In this process, the clinician works with the client to develop a feasible, strategic plan of action. This planning phase can be greatly beneficial for all clients, especially those who have struggled in the past with making changes in their lives. Taking the time, with an ally, to identify the supports and maneuvers that can lead to change helps bolster the odds of success for the client.

Applicability to Correctional Settings and Criminal Justice Psychology

High incidence of recidivism within the criminal justice system reveals what appears to be a

complex relationship with change among offender populations. Often situated in a complex matrix of obstacles, both personal and structural, individuals involved with the criminal justice system can struggle with making the modifications in their lives that will lead to the desistance of crime. Data on criminal justice-involved persons indicate that a majority of offenders have substance abuse disorders and/or mental illness; may have experienced sexual, physical, and/or emotional trauma; lack formal education; and generally come from what can be categorized as disadvantaged backgrounds. Despite the prevalence of these circumstances, the long-standing approach toward offender populations has been punitive and retributory as opposed to therapeutic and rehabilitative. With increased incarceration rates, the data make clear that this approach has failed in its ability to reduce offender populations and increase public safety, suggesting great potential for the application of dynamic, therapeutic approaches like MI to reduce recidivism.

In the field of criminal justice, the power differential between the client and the worker (e.g., probation officer, attorney, judge) is typically great. Many individuals in the system are repeat offenders and have seemingly become accustomed to their cyclical patterns, feelings of despair, and the system's latent threat of punishment. The spirit and processes of MI provide workers within the system a skill set for a nonjudgmental, collaborative approach. Through the use of MI, key players within the criminal justice system can move away from their roles as experts and disciplinarians and begin to forge respectful, trusting, therapeutic relationships with their clients. By eliciting and strengthening their clients' intrinsic motivation and commitment to change, practitioners in the field can help guide clients to meaningful, sustainable changes that benefit not only the clients themselves but also their families and communities. Viewing the offender population with dignity and humanity, respecting their autonomy, and guiding them through the system in a way that enables positive change are steps aimed at reducing recidivism, increasing public safety, and restoring fractured communities. Interfacing with offenders through a restorative approach can help to shift the criminal justice field's focus from punitive to rehabilitative.

Since its introduction to the field of corrections in the 1990s, MI has been explored and utilized in the setting with increasing regularity. The most common application of MI within the field has been the training and coaching of probation staff. With over 3 million offenders currently under community supervision in the United States, probation officers serve in a unique, frontline position. Officers are charged with the duty to monitor their clients and ensure that they are meeting the legal requirements of their sentence, and clients are forced to conduct their everyday lives while simultaneously meeting the demanding needs of their sentence. The use of MI in this particular setting has the ability to mend the often-fractious relationship and great power differential between probation officer and client, potentially leading to fewer infractions and breaking the cycle of recidivism.

Initial research measuring the effectiveness of the approach in the criminal justice field shows promising results. By and large, the data suggest that MI significantly increases an offender's intrinsic motivation to change. While more research must be done in the area, these initial findings exemplify the benefit of and potential for change within the criminal justice arena.
